EMISTRY OF INHALATION ANESTHETICS*

CHARLES BASKERVILLE, PH D, F C S
ofessor of Chemistry and Director of the Laboratory College of the City of New York
NEW YORK

The differing experiences which expert anesthetizers e had in the use of ethyl ethers supplied by various nufacturers in numerous surgical cases have prompted e present investigation of the chemistry of inhalation sthetics These differences are often not to be lained by idiosyncrasy Then, too, the standards down by the various pharmacopeias of the world not uniform In view of this fact alone, a thorough tigation seemed called for Inquiries addressed to consumers of the solvent in manufacturing proc- adduced further need for satisfactory methods of mining the purity of ethyl ether and chloroform, f detecting impurities introduced, or proving their ce if eliminated, in the modification of the raw pl cts used in their manufacture The presence of e amounts of substances has oftentimes been the th of a chemical reaction proceeding in a particular bo ion by virtue of a "catalytic action" So the pres- ar f even traces of certain substances, as for example, di dized compounds, aldehyd, etc, in ether, may have C l some reactions to be incorrectly explained or to d an unusual or unaccounted for route This is bu ubtedly true for many physiologic changes ph investigation of ether and chloroform naturally fo an examination of nitrous oxid and oxygen to esearches have been quite thorough and pursued fo eral years

NITROUS OXID[1]

1793 Deiman and others prepared nitrous oxid by m ing ammonium nitrate essentially the commercial ess for its manufacture to day,[2] as it is made by prod such a mixture of salts that ammonium nitrate prov f the bodies taking part in the reaction the commercial nitrous oxid is apt to contain these possibl es chlorin nitric and nitrous oxids, nitric acid, ia, hydrochloric acid, carbon dioxid oxygen, nitrogen and the rare gases of the air It is usually purified by passing the gas through solutions of sodium ydroxid, ferrous sulphate and sulphuric acid Further purification may be accomplished by the formation of a hydrate below 0 C and heating this hydrate (N_2O, $6H_2O$) by fractional condensation and by fractional distillation (to remove the rare gases of the air), but these methods are not practiced in this country

Table 1 which is self-explanatory, exhibits the results of our analyses of compressed nitrous oxid as supplied by American manufacturers

TABLE 1 — ANALYSIS OF NITROUS OXID OF AMERICAN MANUFACTURE

No	N_2O†	H_2O	CO_2	NH_3	O_2	N_2 etc by Difference	N_2O by Explosion	N_2O by $Cu + CO_2 + H$‡	N_2O by $Cu + H$‡
1	99 7	0 13	0	0 006	*	0 16	97 5	99 4	99 7
2	96 6	0 15	0	0 001	*	3 25	95 0	96 [illegible]	96 6
3	99 5	0 17	0	0 000	*	0 35	97 3	99 5	[illegible]
4	95 9	0 16	*	0 000	*	3 94	94 1	95 [illegible]	[illegible]

* Present † Actual percentage present ‡ New methods of Baskerville and Stevenson

Standards of Purity —Nitrous oxid which is to be used for anesthesia should contain at least 95 per cent of N_2O and no solids, liquids, combustible organic matter, chlorin or other oxids of nitrogen A small amount of carbon dioxid, according to the investigations of Gatch, can have no evil effects If present, however, the percentage should be known

ETHYL ETHER[3]

Ethyl ether is still made commercially by the historical process of treating alcohol with sulphuric acid — hence the misnomer of "sulphuric ether," or "vitriolic ether" — although other synthetic processes have been proposed, some of which have been tried out, but always without commercial success

The quality of ethers on the market depends on first, the purity or grade of the alcohol used, and, second secondary reactions which take place, not only with impurities in the alcohol, but with ethyl hydroxid itself For example, ethyl ether made from ethyl alcohol denatured by methyl alcohol contained other ethers as dimethyl oxid or methyl-ethyl ether not found in the ether made from rectified spirit The generous interpretation of the denatured alcohol act by our government officials whereby alcohol denatured by ether itself may not be used, eliminates these substances Many of the impurities traceable not only to the quality of the raw products used but t [illegible] ndary r [illegible] of their virgin impurities, [illegible] perature, pressure and other conditions, were removable and have in a large measure been removed, or much reduced, by subsequent purification

* Because of lack of space this article is abbreviated in The ournal. The complete article appears in the Transactions of the ection and in the author's reprints

[1] See Baskerville and Stevenson (Jour Ind Eng Chem August 11 No 8) for a detailed account of the preparation analysis and urification of nitrous oxid

[2] It is usually carried out by heating mixed salts as $NaNO_3$ d $(NH_4)_2SO_4$, $NaNO_3$ and NH_4Cl etc

[3] For a full consideration Baskerville and Hamor Jou and On ethyl ether for an Druggist Sept 20 1910

The specific gravity of ether intended for anesthesia should not exceed 0 720 at 15 C, provided that an ether containing minimum quantities of alcohol and moisture is required, an ether, however, which shows a specific gravity of 0 7215 (2 per cent absolute alcohol), 0 7227 (3 per cent absolute alcohol), or even 0.724 (4 per cent absolute alcohol), provided that the sole "impurity" is ethyl alcohol, is acceptable for anesthetic purposes according to various pharmacopeias

Presence of Alcohol in Ether—In this connection it may be stated that for various reasons a pure ether may be diluted with ethyl alcohol when it is to be used for anesthesia Impurities then observed may be due in part to the alcohol used in dilution Practically all ethyl alcohol contains some acetaldehyd

It has been asserted that ethyl alcohol serves as a preservative for ether when the latter is properly stored, which is not true, and small amounts interfere in no way with the application of ether in anesthesia The presence of alcohol is unnecessary except when ether is administered by the drop method In this case the presence of alcohol prevents too rapid volatilization and consequent chilling of the apparatus with which the ether is administered, and the alcohol remaining on the cone lowers the freezing-point of the condensed moisture of the breath The presence of excess moisture in liquid ether should be guarded against, since ether in contact with water, or moist air, in time gives rise to various impurities of an objectionable nature Thus anesthetic ether even of proper grade may develop impurities to be avoided quite as much as if they had been introduced in the original materials or later produced in the manufacture or added in the preparation for distribution in commerce

Assisted by W A Hamor, I have conducted an extensive investigation of the changes which occur in ethyl ether during storage, and the experimental data obtained lead to the conclusion that the oxidation of ether in the presence of moisture is productive of a series of complex conversions, initiated, however, by the formation of hydrogen dioxid

Our experimental work seems to establish beyond any doubt the fact that ether of anesthetic grade contains peroxidized compounds after exposure to varying temperature conditions and sunlight, in the presence of atmospheric oxygen, for considerable periods of time, especially when it is stored in colorless glass vessels, or in badly stoppered tin containers

Acetaldehyd, *the presence of* which may account for some of the observations made in practice, is one of the impurities most likely to be generated by exposing partially filled containers to varying atmospheric conditions for continued periods of time Ether should not be stored in glass vessels for any length of time without being tested for oxidation products before use, and the tin containers should be of such *capacity that they* need not be opened without being emptied when the ether is employed for anesthetic purposes

Since it is highly important that ether intended for anesthetic purposes should be carefully manufactured and properly stored, as prolonged exposure to light and air greatly affect the results of etherization, causing coughing, suffocation, and even dangerous after effects, such ether should always be tested for acidity, peroxids and aldehyd, and the presence of the last should be rigorously guarded against, or the ether, if so contaminated, should be *administered* by a method which eliminates these impurities before it is introduced to the animal system

We have made a study of the value of proposed tests for the impurities in ethyl ether, and used several new and superior ones A scheme for [illegible]mination has been worked out and is now available in literature[4]

CHLOROFORM[5]

Liebig prepared chloroform from chloral and treating acetone with "bleaching-powder" Guthrie and also Soubeiran treated alcohol with "bleaching-pow[illegible]" Scheiing generated his "bleach" in the presence of al[illegible]hol by electrolysis Then "methylated spirit" was us[illegible] whereby so called "methylated chloroform" was obtain[illegible] In 1848 Bottger and others used acetates, and th[illegible] chlorin was liberated in acetone by electrolysis T[illegible] process is used extensively in this country now Metha[illegible] of natural gas has been burned in chlorin, but this process has not proved successful commercially so fa[illegible] *Carbon tetrachlorid, made by chlorinating* carbon disu[illegible]phid, is being reduced by the process of A W Sm[illegible] to produce much chloroform in this country at prese[illegible] "Chloral chloroform" is imported in small quantities

From the variety of *Ausgangs-Material* and differe[illegible] methods used, it is quite evident that crude chlorofo[illegible] may contain a wide range of impurities, which [illegible] vary not only with the materials used, but also [illegible] the conditions of manufacture Alcohol has [illegible]en removed from chloroform by washing with water, [illegible]he chloroform being subsequently dried over cal[illegible] chlorid Potassium hydroxid has been used to re[illegible]ve excess chlorin and acids Manganese dioxid has [illegible]een used to remove sulphur dioxid Chloroform has [illegible]een treated with concentrated sulphuric acid until the [illegible]cid was no longer colored, and then the vapors of [illegible]oroform have been passed through towers of cryst[illegible]lized sodium carbonate, rectification has followed To re[illegible]ove special impurities or decomposition products of the chloroform itself chloroform has been treated with lead dioxid, with potassium permanganate, or with [illegible]ute sodium thiosulphate, or it has been distilled over 2 [illegible]er cent paraffin or poppy oil

"Chloroform Anschutz" is obtained by distilling from crystals of salicylid-chloroform ($C_{28}H_{16}O_8$, $2CHCl_3$) "Chloroform Pictet" is made by chilling chlorofor[illegible] to — 80 C, filtering off the solids produced, and then [illegible]ering *the temperature to* — 82 C *and* drawing off [illegible]e liquid impurities The frozen chloroform is then f[illegible]tioned, the intermediate 80 per cent of the distil[illegible]te being taken

Specific gravity determinations are not to be regarded as criteria of purity beyond indicating the amount of alcohol in chloroform

There has been not a little diversity of opinion among chemists as to the nature and products of the decomposition of chloroform, especially the changes which chloroform undergoes on exposure to air, in fact, this discordance dates from the introduction of chloroform as an anesthetic and prevails to day This condition is ascribable to the many influencing factors occasioned by the *degree of purity of the chloroform under examination* and the extent and nature of the exposure, but is principally due to the failure to consider and cor- [illegible] of only one c rectly interpret the rôle of the general variable, alcohol, and with it the accompanying moisture

[5] The histo[illegible]re purification physical constants decomposition and analysis [illegible] examination of chloroform of all grades [illegible]erville and Steven[illegible] by Baskerville and Hamor, Jour Ind [illegible]st 1912

The products of the decomposition of "pure" chloroform, according to various investigators, may be summarized thus

Chlorin, hydrogen chlorid Morson, Maisch and Hager
Carbonyl chlorid Rump, Regnault
Carbonyl chlorid, hydrogen chlorid Stark, Ramsay, Schoorl and Van den Berg, Dott
Carbonyl chlorid, chlorin Brown, Schacht and Biltz, and Adrian

The formation of carbonyl chlorid alone is definitely agreed on

The decomposition of chloroform has been universally conceded to be an oxidation process It is generally accepted that chloroform is unaffected by light alone, and that light, although it accelerates oxidation, is not a necessary factor in the process (Hager, Rump, Brown, Schoorl and Van den Berg), several investigators, however, appear to have inclined to the view that light favors decomposition (Regnault, Dott)

With regard to the changes which occur in anesthetic chloroform during exposure to air and light there also exists a decided diversity of opinion, principally owing to the fact that no examinations were made during the course of the various investigations, so far as I am aware, for the presence of the oxidation products of alcohol in such chloroform The whole subject required investigation, and accordingly an experimental study of the decomposition of both pure and anesthetic chloroform was carried out It was also hoped to throw light on, if not fully explain, the rôle of alcohol[6] and other substances in the so-called preservation of chloroform, a satisfactory explanation of which has been wanting

Various samples, twenty-three in all, both of pure chloroform[7] and of chloroform containing the usual pharmacopeial amounts of alcohol and water, were exposed in well-stoppered[8] containers of various sizes, these held varying amounts of the samples, and were of both colorless and anactinic glass, such as are customarily used in the trade The exposures were made for different periods of time, but at room temperature, 20 C, from September to May, inside of a window having direct southern exposure The conditions were extreme, but nevertheless were similar to those obtaining in many pharmacies and hospitals

The anesthetic chloroform used was examined prior to the experiments, and only such chloroform as was found to be free from all impurities was used An amount of water, however, equivalent on the average to 5 1 per cent by volume of the alcohol present was permitted Thus each sample was of pharmacopeial grade

The tests applied for the detection of the oxidation products of chloroform and alcohol were those previously proved out in our work Quantitative determinations of the impurities developed were made whenever it was possible to do so

RESULTS OF AUTHOR'S EXPERIMENTS WITH CHLOROFORM

The experimental results warranted the following conclusions

1 The products of the oxidation of pure chloroform are carbonyl chlorid and hydrogen chlorid, which come about according to the reactions

$$CHCl_3 + H\ O + O = COCl\ + HCl - H\ O$$
$$CHCl_3 + H\ O = COCl\ + HCl + H\ O$$

We are convinced that oxidation will not occur if water be excluded and the absolute exclusion of moisture appears to be impossible in practice Hydrogen dioxid is formed, although we were unable to detect it in the chloroform undergoing oxidation and therefore concluded that its existence is ephemeral and oxidation of the chloroform continues throughout the period of the exposure The rôle of the water is that of a true chemical catalyst The decomposition of pure chloroform is accelerated by light as was shown by a comparison of the results obtained in the experiments wherein colorless glass was used with those in which anactinic glass containers were employed Carbonyl chlorid is formed with increased readiness in the presence of acids

The extent of the oxidation is dependent on the nature of the container, the amount of air present the purity of the sample and the intensity of the light to which it is exposed With light alone, when no air is present no decomposition occurs for ordinary periods of exposure and in cases where there is air contact alone and no exposure to light the oxidation is slow

2 The products of the oxidation of anesthetic chloroform are primarily the oxidation products of alcohol and no decomposition of chloroform itself occurs while the oxidation of alcohol proceeds When the oxidation of alcohol reaches a maximum, decomposition of the chloroform goes on as in the case o pure chloroform with the exception that chlorinated erivatives of the oxidation products of alcohol may [illegible] The decomposition of the chloroform itself is re[illegible]d, even prevented so long as oxidation of the alco[illegible] proceeds, and the retardation is consequently dependent on the amount of alcohol present The extent of the oxidation is subject to the conditions referred to in the oxidation of pure chloroform It is important to note, however that anesthetic chloroform nearly always contains water, the usual amount being about 0 05 per cent by volume according to my experiences

The preservative action of alcohol is due to the combination of the retarder with certain of the reacting substances and any substance soluble in chloroform and readily oxidizable will exert an inhibitory effect on the oxidation of chloroform it elf, for example sulphur and many other substances All compounds which have been found to serve as preservatives of chloroform are reducing agents and the effect is due to their capacity for oxidation

THE STORAGE OF ANESTHETIC CHLOROFORM

Anesthetic chloroform should preferably be furnished in vials ampules or bottles of high grade anactinic glass containing about the quantity sufficient for one narcosis, and at the most not more than can be used within several days If for any particular reason chloroform is ordered in a large container it is advisable immediately after opening it to subdivide the entire remaining contents into 2 ounce bottle taking care to fill the small bottles completely It is important to see that the bottles are first completely free from water, and empty bottles should not be refilled without thorou[illegible]

---

[6] The amounts of alcohol stated as permissible in the various official chloroforms intended for anesthetic purposes are as follows

Belgium	1 0 per cent
Denmark	1 0 per cent
Sweden	0 5 1 0 per cent
United States	0 6 1 0 per cent
France	0 005 part by weight.
Italy	0 5 per cent
S[illegible]	[illegible] cent, absolute

7 [illegible] elimination Other factors [illegible] to the method of the [illegible] constants were perature and moisture The anesthetics are [illegible] at 15 4 C the system at [illegible] Switzerland [illegible] ature This may were employed [illegible] bottles were plished his chloroform was prep the case of ether and author and was absolutely through heated water which boiling point + 61 2 C at 760

8 No cork stoppers unpro[illegible] removes the aldehyd but In the experiments on pure c[illegible] nt used solely [illegible] in hydre (Gwathmey method)

unmindful of its dangers and limitations We have about ten compound, complicated and complex nitrous oxid and oxygen instruments on the market, each costing from $100 to $300, weighing from 40 to 80 pounds, and occupying as much space as a sewing-machine Many of these instruments have so many valves and other parts as to suggest the need for an engineer's or chauffeur's license I am sure that we are a trifle dishonest at times about this sequence, and that though we use morphin, nitrous oxid oxygen and plenty of ether we call it a nitrous oxid and oxygen sequence

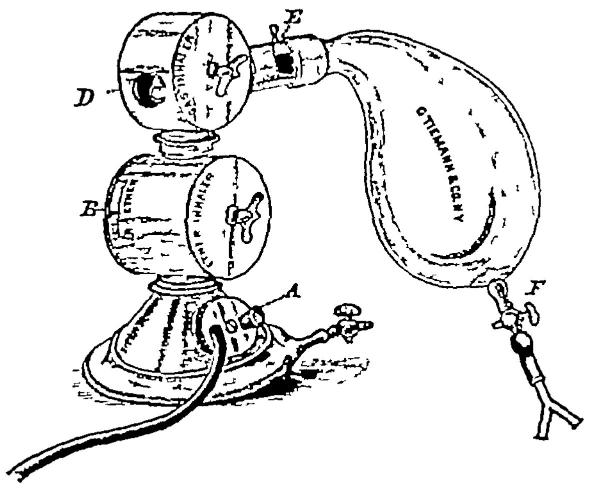

Fig 6 —The Bennett inhaler

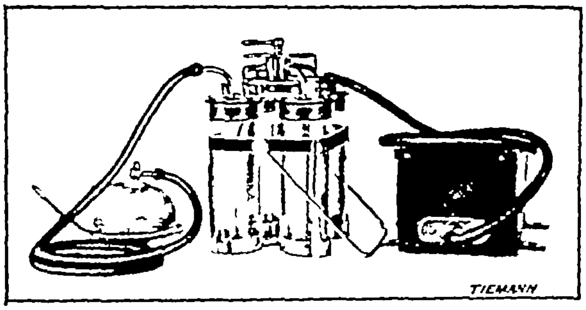

Fig 7 —Four bottle Junker vaporizer as modified.

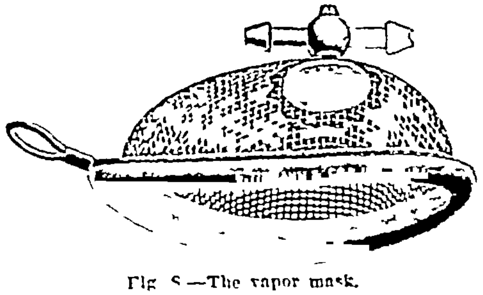

Fig 8 —The vapor mask.

Nitrous oxid and oxygen can easily be given in the following ways (1) Simply use a Y-shaped tube at the end of the gas-bag to connect the two gases (Fig 6 F) (2) Lead the oxygen direct from the tank to the Bennett inhaler by a rubber tube through one of the air holes in the face piece plugging the other air hole with a cork (Fig 6 A) The Bennett inhaler is used chiefly to induce anesthesia with the gas-ether sequence This instrument weighs only 2½ pounds, costs less than $50 and may be transported easily

My four-bottle modified Junker vaporizer (Fig 7) is an instrument allowing the easy and quick use of almost any anesthetic in any strength or combination and is particularly useful for head and neck operations One bottle can be used for warm water to warm the anesthetic vapor Personally I prefer to use it as a means of catching any overflow that may result from filling the bottles too full or when too much pressure is used Usually the other three bottles are used for ether and chloroform Two bottles are filled with ether, and when one becomes too cold, as often happens after using it for a few minutes, or becomes empty, the other bottle is used The vapor can be forced by a hand bulb such as is usually attached to a Paquelin cautery outfit or a small foot-pump or bellows The face or vapor mask which I use is similar to the ordinary face mask with an arrangement in the top for the distribution of the vapor in front of the nose (Fig 8) This vapor mask is useful in giving oxygen with ether or chloroform by the drop method The advantages of the so called vapor method are (1) less anesthetic is used (2) there are less nausea and vomiting, (3) the breathing is more like that of normal sleep, (4) the apparatus is out of the surgeon's way (5) the anesthetist's hands are free, (6) it will be found easy to change from one anesthetic to another, or to form any combination

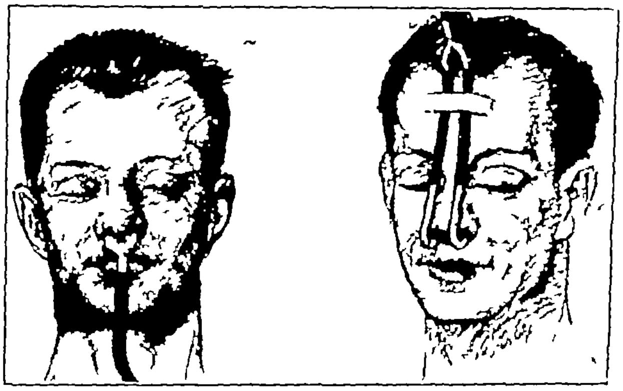

Fig 9 —Glass nasal tubes for general anesthesia in use

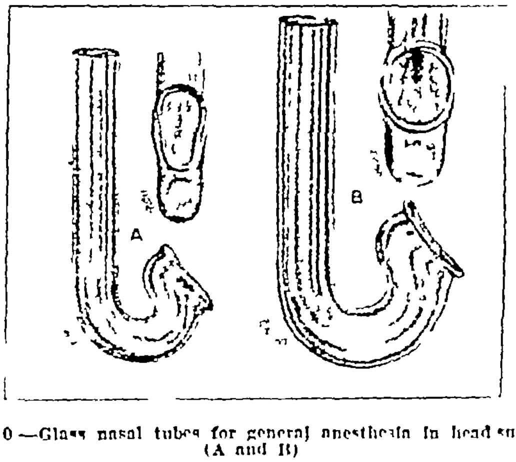

Fig 10 —Glass nasal tubes for general anesthesia in head surgery (A and B)

For special head cases I use glass nasal tubes (Fig 9) which have these advantages over the rubber tube (1) They allow the anesthetic vapor to become warmed by passing through the nose (2) they are more safely and easily introduced into the nose (3) they do not cause nasal hemorrhage, (4) they are not apt to become obstructed by blood and mucus, (5) they remain in position much better than do rubber tubes, (6) they are much easier to clean and sterilize

They are made in three sizes accompanied with a Y-shaped glass connecting tube which is used for operations on the upper part of the head (Figs 9 and 10)

1925 Seventh Avenue

SPINAL ANALGESIA—DEVELOPMENT AND PRESENT STATUS OF THE METHOD

WITH BRIEF SUMMARY OF PERSONAL EXPERIENCE IN 1,065 CASES *

WILLIAM SEAMAN BAINBRIDGE, ScD, MD
NEW YORK

Spinal analgesia proves no exception to the general rule which applies to new methods Its early development was fraught with mistakes some of which were serious and even fatal When it was heralded throughout the world that Bier had successfully injected cocain into the spinal subarachnoid space, many surgeons adopted the method It was a new field and little was definitely known concerning the physiologic aspects of the question, and little more with reference to the therapeutic phases of the subject It was but natural that as the literature of spinal analgesia developed, the number of unfortunate experiences multiplied It was inevitable, too, that enthusiasm should wane, and that the further development of the method should be left to a limited number of surgeons who recognized in spinal analgesia a procedure of distinct advantage, with a definite field of usefulness

Following Bier's first demonstrations of the surgical application of spinal analgesia, report of which was published in 1899, the method was quite extensively employed for two or three years Accounts of its use then disappeared almost entirely from medical and surgical literature, though it was not abandoned by the few earnest advocates of the method The revival of the subject in the literature about five years ago is familiar to all It is safe to assume that spinal analgesia is now permanently established among recognized surgical procedures, and will never again so nearly approach abandonment as it did during the short period of quiescence which followed its first few years of popularity

A just estimate of the merits of any method can be reached only by a study of the accumulated experience of many observers It is manifestly impossible on this occasion to trace the evolution of spinal analgesia by a review of the literature which chronicles the findings of the large number of surgeons who are now employing or have employed the method

During the early stage of the development of spinal analgesia cocain and eucain were the agents most generally employed This fact probably accounts for many of the adverse opinions formed of the method Eucain gave a "patchy and hence altogether unsatisfactory analgesia Cocain was not entirely satisfactory partly because of the reckless dosage employed by many surgeons and partly because of the difficulties experienced in sterilizing the drug without destroying its analgesic effect or decomposing it in such a way that its by-products gave rise to unpleasant accompanying or postoperative phenomena Bier early protested against the reckless manner in which cocain was being employed, and against the dangerously large doses which some operators used He made a plea for an effort to find less harmful drugs for the production of spinal analgesia

A very important part of the evolution of spinal analgesia has been concerned with the discovery of other drugs and other combinations which would give a controllable analgesia, and at the same time lessen the dangers and eliminate the frequently disagreeable accompanying symptoms associated with the method In the endeavor to find such a drug a great deal of careful experimental work has been conducted by different investigators The results have been remarkably successful and have given to the method a definite field of usefulness

My experience with cocain was not so unfavorable to that drug probably because at an early stage of the development of spinal analgesia I formulated a plan of sterilizing the agent[1] which insured not only a sterile but a fresh and active solution free from the harmful by-products so often claimed to be present and generally attributed to the methods of sterilizing by heat

It is not necessary here to enter into the question which from time to time has been raised concerning the validity of the claims that cocain is decomposed by heat and its analgesic properties destroyed as a consequence Whether correct or incorrect the impression has gained currency that boiling decomposes solutions of cocain Various methods of sterilizing this agent have therefore been suggested The simplicity of the method which I have employed renders it of value for emergency work, where a rapid method is required to secure a sterile, potent solution The method, which is applicable to other analgesic agents as well as to cocain is as follows

Five grains of fresh cocain crystals carefully weighed are placed in a sterilized measuring glass Two drams of strong ether are added and mixed thoroughly with the cocain crystals by means of a sterilized glass rod until a paste is formed The mixing process is continued until all the ether is evaporated and a dry powder is obtained One-half to 1 ounce of boiled filtered water or sterile normal salt solution is then added One-half ounce makes practically a 2 per cent solution and 1 ounce a 1 per cent solution The dosage varies according to the age of the patient the region to be operated on etc from 5 to 25 minims of the 2 per cent solution and from 10 to 40 minims of the 1 per cent solution

The crystals, if kept dry do not deteriorate as do other forms of the drug It is advisable however if possible to employ only fresh crystals or to be sure that they have been kept perfectly dry With active cocain at one end of the scale and inert cocain at the other there are various grades of potency from an analgesic point of view The exact cause of this variation is a matter of dispute some holding that it is due to the heat sometimes employed in sterilization others denying the correctness of this assertion The members of the Section on Pharmacology and Therapeutics will doubtless clear up this point in the discussion

Following the suggestion of Bier that less harmful agents be found for spinal analgesia experimentation has led to the employment of the following [illegible] stovain novocain tropacocain beta-eucain [illegible] lactate alypin holocain hydrochlorid [illegible] anesthesin and other agents Cocain, stovain, novocain and tropacocain are the drugs most generally used, with stovain, perhaps, in the lead

---

* Read in the Symposium on Anesthesia in the Joint meeting of the Section on Pharmacology and Therapeutics and the Section on Pathology and Physiology of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912

[1] Bainbridge Med Rec New York Dec 17 [illegible]

Other drugs than cocain having been found available for spinal analgesia, attention was next directed toward making such combinations of these with other substances as to render the solution heavier or lighter than the cerebrospinal fluid, the object being to avail oneself of gravity in controlling the height of the analgesia Experimentation along this line has led to some very interesting results, and has evolved three general classes of solutions (1) those of lighter specific weight than the cerebrospinal fluid, (2) those of approximately equal weight, (3) those of heavier weight

To the first class belongs the so-called "diffusible" solution employed by Babcock, in which alcohol is used to render the fluid lighter than the cerebrospinal fluid

To the second class belong the simple solutions of the analgesic agent with water, with water plus cerebrospinal fluid, with cerebrospinal fluid alone, or with normal salt solution

To the third class belong the so-called "non-diffusible" solutions, which are rendered heavier than the cerebro spinal fluid by the addition of glucose, dextrin or gum arabic

To any of these solutions may be added, if desired, epinephrin or some similar product, as employed by Bier, Gray and many others, or strychnin, as suggested by Jonnesco

In 988 of my 1 065 cases simple solutions, of the second class, were employed, the agent being sterilized after the manner described, and dissolved in plain sterile water, without the addition of any other drug In over 500 of the 988 cases cocain was used In the remainder the various other agents and combinations were employed I now use, as a rule, stovain or tropacocain, because fewer unpleasant symptoms are apt to ensue, but I do not hesitate to employ cocain

In the 1,065 cases there was one death (with the diffusible stovain solution, probably due to status lymphaticus), one case of temporary partial paralysis with complete recovery,[2] one case of failure due to so-called "dry spine," in which puncture at different levels failed to bring cerebrospinal fluid, two cases with alypin, in which there was considerable respiratory depression, and one case of idiosyncrasy in which, after several attempts by spinal and local injection, the analgesia was almost nil In all the other cases there were no accompanying or post-operative symptoms of permanent or serious moment

ILLUSTRATIVE CASES WITH THE THREE CLASSES OF SOLUTIONS

SIMPLE SOLUTION (COCAIN WITH WATER)

Case 1—J P D, aged 31, was operated on Nov 27, 1902 (case of Dr William T Scovil, of Richmond Hill Long Island), under spinal analgesia, which I administered The patient had been operated on two years before by Dr George Ryerson Fowler for appendicitis, at which time ether anesthesia was employed The patient suffered for a year and a half from postanesthetic asthma of such severity that it was necessary for him to sit up at night in order to breathe This gradually subsided and for six months before I saw him he had not been troubled with it When I was called in consultation, the patient was suffering from multiple strictures, which had become so tight that there was almost complete retention of urine A filiform bougie could not be passed Albumin and casts were present in the urine Chronic endocarditis further mplicated the condition The patient's testimony was absolutely necessary in a forthcoming murder trial in which circumstantial evidence was so strong against the defendant that a verdict of guilty was almost a certainty Nothing but the patient's testimony could save the man

Treatment—To operate under inhalation anesthesia was practically impossible It was determined, therefore to employ spinal analgesia Cocain, 20 minims of a 2 per cent solution, was injected and external and internal urethrotomy performed Analgesia lasted two hours and ten minutes The patient read and smoked during the operation In two weeks he went into court, gave his testimony and cleared the defendant. The patient, who is still living and in a fair degree of health, has never suffered from asthma since the operation under spinal analgesia—an interesting coincidence at least

Case 2—Mrs M D, aged 43, was admitted to the New York Skin and Cancer Hospital in October, 1911 Examination revealed a large deep tuberculous ulcer of the left leg, 6 by 5 inches in diameter, of three years' duration On Dec 20, 1911 the ulcer was excised, and the surface exposed to fulguration according to the de Keating Hart method, with the long high frequency, high tension, electric spark Analgesia in this case was induced by means of 20 minims of a 2 per cent solution of cocain Eight minims injected at first proved insufficient, and after ten minutes another injection of 12 minims was made Analgesia was complete to the nipple line in four minutes and lasted over an hour There were no accompanying or postoperative symptoms of any moment, convalescence being entirely uneventful

GLUCOSE EPINEPHRIN STOVAIN SOLUTION (NON DIFFUSIBLE)

Case 3—L L, female, aged 58, was admitted to the New York Skin and Cancer Hospital, March 18 1911, for operation for lipomas of the abdominal wall, papilloma of neck angiomas of abdominal wall and varicose veins of the legs The operation was March 20, 1911 Various growths were removed, and the varicose veins excised Analgesia was induced by the glucose epinephrin stovain so called non diffusible solution obtained from Gray, of London one ampule, 2 c c, 3 per cent stovain being injected Adjuvant medication consisted of strychnin, 1/60 grain, and nitroglycerin, 1/200 grain Analgesia extended to the neck, and lasted for one hour and fifty five minutes There was no nausea, no vomiting, no headache, or other unfavorable symptoms The patient was cheerful throughout the operation, her facial expression giving no evidence of pain or distress Recovery was uneventful

The only death which I have to chronicle in my 1,065 cases occurred when the Babcock "diffusible" solution was employed It may be stated in advance however, that the fatality is not necessarily attributable to this agent

STOVAIN ALCOHOL WATER (DIFFUSIBLE)

Case 4—The patient, a male child, aged 2, on my service at Randall s Island, New York City Children's Hospital and School, was in very poor general condition, with chronic bronchitis, some dulness in the chest and distressing inflammation and prolapse of the rectum Operation was definitely indicated, and inhalation anesthesia was positively contraindicated It seemed justifiable, therefore, to attempt to relieve the condition by operation under spinal analgesia An injection of 0 5 c c of the Babcock diffusible stovain solution was employed The child died almost immediately after the injection was made Autopsy was not allowed, but from the apparent slight enlargement of the thymus gland which was present, the dulness in the chest, and the general appearance of the child, it may be that death was due to that more or less mysterious condition known as status lymphaticus We may give the diffusible solution the benefit of the doubt

The following case illustrates the successful application of the method by means of the diffusible solution

Case 5—J R, female, aged 50, was received at Randall s Island Operation, Dec. 14, 1911, consisted of panhysterectomy for fibroid tumors of uterus and cystic ovaries, the incision and suture of "Lane s bands" and appendectomy Preliminary medication consisted of 1/4 grain mo p'un

and 1/200 grain atropin hypodermically half an hour before operation Spinal puncture was made in median line between first and second lumbar vertebrae, 3 c c of stovain alcohol solution injected, at 10 15 Analgesia was complete to nipple line at 10 19 Median abdominal incision was made at 10 25 patient experienced no pain or discomfort Exploration revealed three distinct peritoneal bands narrowing the lumen of the ileum and causing marked angulation at the crest of the pelvis These were sectioned and sutured and the appendix removed This part of the operation was completed by 10 45 and panhysterectomy begun At 11 o'clock the patient complained of discomfort due to the stretching of the abdominal wound, but cutting, suturing or clamping the tissues caused no pain Her condition at this time was excellent At 11 30 patient asked for a drink of water, which was given her, with a small quantity of whisky Respiration and pulse were regular, and the expression of the face revealed no real discomfort There was no nausea, no vomiting and no coughing at any time during the operation The color of the skin remained good throughout Operation was completed and abdominal wound closed at 12 noon Patient left table at 12:05, talking quietly, and in excellent condition Analgesia persisted for one hour after completion of the operation At no time did the patient's temperature rise above 101 degrees F There were no postoperative complications recovery was uneventful, and at the end of the third week the patient was walking around the ward perfectly well

The patient in this instance was an ideal illustration of the field for spinal analgesia She was old beyond her years, with some thickening of the arterial walls, with abnormally small kidneys, excreting urine of low specific gravity, with some albumin and casts There was no postoperative interference with the action of the kidneys such as would very probably have occurred after the administration of ether

With certain notable exceptions, both the experimental and the clinical investigations of the early period of the evolution of spinal analgesia were concerned with the production of analgesia below the diaphragm, and its application to the surgery of these regions It is not to be wondered at, however, that the advocates of the method were unwilling, in many cases, to rest with this limited field of application to the lower parts of the body, and that they began to extend it to the parts of the body above the diaphragm

Tait and Caglieri of San Francisco, Morton of the same place, Chaput of France, and others, performed operations on various parts of the body above the level of the diaphragm, as early as 1900 thus antedating this particular part of the work of Jonnesco of Bucharest by about eight years Tait and Caglieri, in 1900 reported three cases in which cocain was injected into the sixth cervical space, without untoward effects The patients were examined weeks after the injection and found to be free from any complication Similar results were obtained by others

So far as I have been able to ascertain, the work of Tait and Caglieri, Morton, Chaput and others with high injection has not been followed up with further clinical applications, and for this reason perhaps originality in this regard has been generally accorded to Jonnesco The "new method" of spinal analgesia reported by Jonnesco in 1908 consists in piercing the spinal column at all levels, according to the operation and injecting stovain, novocain or tropacocain with strychnin, into the subarachnoid space As is well known, Jonnesco considers the fact that the respiratory nerves are not involved in the high injections as due to the influence of the strychnin

I have never employed the high injection method of Jonnesco, in either the original or the modified form (in which he confines the injection to the superior dorsal and the dorsolumbar sites) I have been able however in some instances to operate on practically any portion of the body under spinal analgesia as induced by the various solutions plus the head high or the head low position of the patient Years ago I used strychnin and glonoin hypodermatically as supportive and corrective medication at the time of the spinal injection The only thing new in Jonnesco's method so far as strychnin is concerned is injecting this drug with the analgesic agent, into the canal

The evolution of spinal analgesia was not completed with the discovery of less harmful agents as suggested by Bier With the perfection of combinations of the analgesic agents with other substances giving a more or less diffusible solution and a consequently more or less controllable analgesia and with the extension of the application of the method to the upper part of the body, the indications and contra-indications for the method have also been carefully studied and no inconsequent part of its development is concerned with the widening of the scope of spinal analgesia

One of the most telling illustrations of this increased sphere of application is its use with children In the earlier days of spinal analgesia perhaps the majority of writers on the subject named infancy and childhood among the contra-indications Even now many advocates of the method do not approve of its use in this class of patients

In the early stage of the application of spinal analgesia I began to employ the method being particularly interested at that time in its use in young children Several cases of children operated on under spinal analgesia were reported by me,[3] the youngest being 3½ the oldest 11 years old The former patient was apparently the youngest on whom the method had been employed at that time I reported an additional series of forty cases,[4] twenty-four of which were given in detail the youngest being 7½ and the oldest 19 years of age In July of the same year I reported twelve operations[5] on infants and young children the youngest of this series being 3 months and the oldest 5 years of age

Since that time a large number of children have been operated on by various surgeons the most notable series of cases being that reported by H Tyrrell Gray of the Hospital for Sick Children London He employed the method in all abdominal work on children holding that when it is used the mortality record in such cases is materially lowered

Along with the perfection of the method in the matter of agents, sites for injection scope of application etc, there was much to be evolved with reference to the preliminary preparation of the patient the selection of the analgesic agent best suited for the given case the careful estimation of the dose required for the individual patient and the actual technic of injection

As the method has been developed, various needles and syringes for the injection have been devised and the technic has been varied to suit the ideas of the *individual operator* Time does not permit nor is it necessary to detail the different modifications of the method The technic which has answered my needs best is given below

PRELIMINARY PREPARATION OF PATIENT

Preliminary preparation of the patient [illegible] diet catharsis etc which is of great importance [illegible] inhalation anesthesia is not so essential in spinal analgesia except in operations on the intestines. In a certain percentage of cases incontinence of urine and feces occurs from relaxed sphincters when rectum and bladder have not been emptied. Patients coming into the hospital from the street, with no preliminary preparation, have been operated on as successfully, and with as few accompanying and postoperative phenomena, as have those who have been subjected to the most careful preparatory care. Generally speaking, however, attention to all details which conserve the patient's vitality and comfort should be observed.

[5] Arc [illegible] Ped July [illegible]

A hypodermic injection of morphin (1/6 to 1/4 grain), combined in some cases with atropin or scopolamin, may be given half an hour before spinal puncture. It serves to tranquilize the patient and to make him less susceptible to any possible pain or discomfort contingent on the initial procedure. Bromids instead of morphin may be given the day before or nitroglycerin (1/200 to 1/100 grain) may be advantageous, administered at the time of injection. Strychnin (1/60 grain) given subcutaneously at the time of the spinal injection is supportive. Combined with nitroglycerin it lessens the danger of headache, shock and other disagreeable symptoms.

No preliminary medication is given to children.

APPARATUS

The apparatus for giving the injection of the analgesic agent consists of a syringe and two cannulas.

The syringe, which is made by Ford and Company or the Kny-Scheerer Company of New York, is entirely of metal, including the piston, so that it expands uniformly on boiling. It has a capacity of 5 c.c., the corresponding quantities in the two systems being graduated on the piston.

The cannulas are made in two sizes, of three lengths. The points are ground short and beveled, with a cutting-edge all round. The shank is of flexible metal, so that it will bend without breaking. The cannula slips on a ground joint, fitting accurately the handle, without washers or screws. The proximal end is fitted with a handle which can be firmly grasped. Through the cannula runs a stylet, the proximal end of which is rounded, knob-like, so that it can be pressed against the base of the index finger, adding firmness of grip.

The entire instrument can be taken apart and thoroughly sterilized.

TECHNIC OF INJECTION

The usual aseptic precautions are observed. The site of puncture may be cleansed in the usual way, by scrubbing, etc., or by painting the skin with tincture of iodin. The patient, in the sitting posture, the feet hanging over the side of the table, with the puncture site painted with iodin, is draped with a sterilized sheet. This sheet has cut in it a hole or window large enough for purposes of injection. The operator in making his examination and identification of landmarks runs no risk of contaminating his hands by contact with skin surfaces which have not been rendered aseptic.

The site of puncture is now determined in the following manner:

1. The highest points on the crests of the ilia are located. On this level is the spinous process of the fourth lumbar vertebra.

2. The sites of the second, third, fourth and fifth lumbar vertebrae are marked.

3. The thumb is placed in the space between the twelfth dorsal and first lumbar, second and third, third and fourth, or fourth and fifth lumbar vertebrae, according to the selection of site, *at the mid-point between the two*. One half inch to either side of this is the site for the puncture. I usually inject between the fourth and fifth *or third and fourth lumbar vertebrae.*

The puncture point being located, the assistant plays a spray of ethyl chlorid on the area, or, if preferred, a preliminary subcutaneous injection of cocain or other local analgesic agent may be given. A small incision *is now made through the true skin, which may be* rendered hemostatic as well as analgesic by the ethyl chlorid.

The needle is passed through the incised skin and subcutaneous tissue, *straight forward*. The head is then depressed, the point being made to go upward, forward and inward toward the median line. It is inserted from 1½ to 2½ inches, according to the thickness of the *patient's body.*

When the needle is felt to impinge on the bone surrounding the foramen, it is depressed a little more and *pushed forward when it comes on the ligamentum subflavum, then the dura mater. In piercing the ligament* and dura there is a peculiar sensation like the "popping" of a membrane. This signifies the entrance to the subarachnoid space.

*The cerebrospinal fluid escapes under ordinary circum*stances. If it does not flow freely something is wrong. The needle may not have entered the right place, or it may be clogged. A stylet should not be inserted into the needle. Another syringe should be ready, and with this, if one cannot draw out blood or fluid, the needle should be withdrawn entirely and then, after being rendered patent, reinserted. I prefer not to proceed with the *injection unless the fluid issues with at least* an approximate quantity and tension. Others, notably Gray,[6] are not agreed on this point, being willing to *proceed with the injection when the fluid issues only in* slow drops, or when it is slightly blood-stained.

In some cases, despite careful technic and repeated attempts at different sites, no cerebrospinal fluid is obtainable. Such cases have doubtless led to the expression "dry spine," but it is rather to be inferred that they come under the category mentioned by Gerstenberg and Hein,[7] Lusk[8] and others, in which the arachnoid membrane is adherent to the posterior surface of the cord at the levels entered, so that no fluid is obtained for the reason that at the given locality, the subarachnoid space is obliterated posteriorly. I have had one such personal experience. Despite four attempts, in each of which the canal was entered, two between the fourth and fifth, one between the third and fourth, and one between the second and third lumbar vertebrae, no fluid was obtained. The attempt was then abandoned and the operation (appendectomy) successfully performed under ether anesthesia.

The analgesic solution is now injected slowly. The obliquity of the passage of the needle has the advantage that no tract is formed for the fluid to follow as the needle is withdrawn. The body of the vertebrae in front should not be touched with the needle, because of the presence there of a large plexus of blood-vessels. When the needle is withdrawn a cotton and collodion dressing is applied.

If low analgesia is desired for operations on the lower part of the body, the patient should be allowed to sit up *for a few minutes after the injection, or the head should* be elevated, when solutions of the same or heavier specific weight than the cerebrospinal fluid are used If the lighter fluid is employed, it must be borne in mind that the head must be lowered *at once* after the injection to prevent the rapid diffusion of the analgesic agent and the danger of death from respiratory paralysis When high analgesia is desired for operations on the upper parts of the body, the patient may be placed in a more or less marked Trendelenburg position, with the heavier solutions The "diffusible" solution may be used if after the initial lowering of the head, the head of the table is slowly and carefully elevated My own feeling is that operations on the head and neck should not be undertaken under spinal analgesia unless other methods are absolutely contra-indicated and operation is essential

SUMMARY

From the weight of conflicting testimony with reference to the indications and contra-indications for spinal analgesia, it may be deduced, in a general way, that, granting the need of operation and the impracticability of local or regional analgesia *the indications for spinal analgesia are the contra-indications for inhalation anesthesia* So far as the character of the operative procedure is concerned, there are practically no contra-indications to the employment of spinal analgesia A person already in marked shock or profoundly septic should not be subjected to this procedure A number of surgeons with wide experience accept practically no limitations to its use Some operators firmly believe that in certain cases this method is safest and best

The real objections to spinal analgesia in my opinion are

1 The operator is absolutely committed to the dose, whatever it be It can be increased by an additional injection, but it cannot be decreased once given With the changes in the position of the patient, with carefully graded dosage, control can be exercised

2 In prolonged operations the analgesic effect may pass before the surgical procedure is finished In some cases, as in laparotomy, it is quite inconvenient to turn the patient over for another injection

It would be safe to assume that even its most enthusiastic adherents would not advocate the usual employment of spinal analgesia by the surgical novice It must, therefore, continue to occupy a somewhat limited sphere until further accurate and scientific experimentation has led to more certain conclusions with reference to the physiologic action of the agents employed and the dosage in which they may be used to obtain a given result Until such information is definitely in hand spinal analgesia should be employed, as a rule only by those experienced with the method and having careful technic

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS BASKERVILLE, ALLEN, GWATHMEY, MILLER LUMBARD, TETER AND BAINBRIDGE

Dr. F J Cotton Boston The question of doing better work in anesthesia is largely one not of diminishing the deaths 'on the table' but of diminishing those indirectly due to the anesthetic There are for instance the deaths from ether from lung complications. It was a short series of deaths from that source that made me take up nitrous oxid oxygen anesthesia As Dr Teter has said it is the anesthetic of choice for routine work when it can be administered by experts Both this and spinal anesthesia are expert propositions they will not become surgical routines for big hospital clinics That however, is no reason against their use where we can have our own way

I have not had a large experience with spinal anesthesia I think that proper administration makes it safe and satisfactory I have had it given a good many times by Dr Allen and Dr Richardson of Boston, and have found it satisfactory The cases in which it seems to me that it would not be satisfactory to use any other form of anesthesia are those of diabetic gangrene and those of seriously damaged kidneys These patients do better under spinal anesthesia and I have been afraid to use nitrous oxid on them The objection to spinal anesthesia in addition to the fact that it requires an expert to administer it is twofold first, on the part of the patient and secondly, on that of the surgeon First, there are patients on whom it cannot be comfortably used, even if one anesthetize such a patient at the head by talking to him he is more or less nervous Second, it takes long practice to do work with any kind of anesthesia when consciousness on the part of the patient is not abolished To do good work under such conditions takes a rather callous temperament or long practice There is great convenience in having a visible supply of gas Oxygen is the only gas of which it is important to have a visible measure but it is convenient to have a visible supply of both Some form of bubbling arrangement is necessary— to enable one to see whether the oxygen is flowing The development of cyanosis is so prompt under nitrous oxid and oxygen that if there is any hitch there is trouble very soon Anything that gives information on this point is rather worth while Dr Teter has not spoken of the furthering of an even flow by working from low pressure This advantage is commonly accepted to-day, though it is relatively new in the handling of this anesthetic method

Prof Yandell Henderson New Haven Conn I urged yesterday in the House of Delegates (and it seems to me that the matter of statistics tends to bear out the point) that deaths under anesthesia are not really due to anesthetics, but to anesthetists That is if we are going to diminish the deaths under anesthesia we must have capable anesthetists— I am not giving an expression of opinion one way or another as between nurses and interns The principal point that the Committee on Anesthesia urged was that everything should be done that can be done to recognize anesthetists—to have a department of anesthesia for every large hospital and to put it under the control of the attending anesthetist, as the medical or surgical work is under the control of the attendant in medicine or surgery This work should be managed by the attending anesthetist just as it is by Dr Allen at the Massachusetts General Hospital This is of the utmost importance Dr Teter spoke of the quantity of carbon dioxid that is allowable In an early paper, I set the limit at 5 per cent That is too low, but there were not sufficient data at that time to enable us to know how much would be safe It is clear now that it is quite safe to go to 10 per cent, and very likely 15 would not be dangerous

The New York Society of Anesthetists, which was organized last winter, has been the means of bringing the anesthetists in the neighborhood of New York into personal contact, which is important for their mutual advantage and the advancement of anesthesia, and they have felt that it would be well to have a national society of anesthetists It seems to me that to bring the anesthetists all over the country into contact and give them a feeling of solidarity so that they may work together and insist on their rights is most necessary

Dr W Wayne Babcock Philadelphia My experience in spinal anesthesia does not date back so far as Dr Bainbridge's but eight years ago I began to use spinal anesthesia and since then I have employed it in nearly all cases in which the operation was below the level of the nipple except when the patient or the family physician expressed a prejudice I began with heavy solutions and found difficulty in securing uniform anesthesia Gradually I worked away from the heavier solutions and used the lighter, and found that the range of the anesthesia became greater Finally by adding alcohol to reduce the specific gravity, I found I could produce an anesthesia that would involve any part of the body even to the top of the head. The specific gravity of the anesthetic being less than water, if the patient sat erect it would soon rise to the upper cord. This fact involved certain danger, and I soon discarded the high anesthesia, and as a rule limited the use of the anesthetic to operations below the nipple. There is an apparent general misconception as to the nature of spinal anesthesia; it is not a cord anesthesia but a nerve-root anesthesia. Therefore with higher injections, the patient may be completely paralyzed in the upper part of the body, but still capable of using the legs and with tactile and other senses preserved in the feet, showing that the conducting paths in the cord functionate although certain nerve roots are involved. This is important, as when the anesthesia is rather high, paralysis of the nerves controlling the diaphragm results in the abolition of diaphragmatic breathing. As this occurs, the chief muscles of the chest having been thrown out of function, the patient may by accessory muscles make ineffective efforts toward respiration. If such a patient be left alone, he will die; but if artificial respiration be instituted, even though the dose of the spinal injection be large, the patient will again start breathing, although perhaps not for fifteen or twenty minutes. The anesthetic has little influence on the heart, and by artificial respiration the patient may be kept alive, even after tremendous doses of the anesthetic.

Spinal anesthesia is contra-indicated in conditions that prevent the efficient use of methods of artificial respiration. It is especially useful in heart disease and in the other conditions described by Dr. Bainbridge. In regard to the objections, first that the patient is conscious, Dr. Bainbridge has shown how patients may almost enjoy the operation. Some, indeed, do seem to enjoy it. Those who are nervous, on the other hand, may readily have their higher centers abolished by injections of scopolamin and morphin. There is more and more a tendency to use narcotics so that the patient comes down to the operating room in a "twilight sleep."

Dr. R. C. Coburn, New York: Clover was the originator of the beneficial method of rebreathing, but it was on a very unscientific basis until the work of Henderson, who presented it in such a light that it is now susceptible of almost universal application. I strongly disagree with one of the speakers, who said that nitrous oxid is administered by rebreathing on account of the money that this saves, and that there is no principle involved that renders it safer, such as the matter of the increased carbon dioxid in rebreathing. While it is true that under nitrous oxid anesthesia there is less shock than under any other form, and that the anesthetic per se does not produce shock, yet under its influence there is a smaller amount of carbon dioxid in the blood, and therefore a greater call for its retention than with any other anesthetic. As a corroboration of Henderson's theory as to the effect of the retained carbon dioxid in the administration of anesthetics I want to cite personal observation that in abdominal operations in which the viscera are exposed and there is opportunity for the carbon dioxid to transpire into the surrounding air, the patient will tolerate a double amount of rebreathing, i. e., twice as much as in other conditions in which there is little exposure of the capillary blood-vessels.

A point in the administration of ether that corroborates this is that when a patient is under a light anesthesia the shock is greater than under deep anesthesia, especially in abdominal operations. It is my experience that in the administration of ether when one uses an extra amount of rebreathing, keeping the carbon dioxid at normal or more, the patients will undergo operations under light anesthesia with practically no shock. I believe that this is due to the increased carbon dioxid provided through the extra amount of rebreathing. In abdominal operations in which the operation has been especially made the carbon dioxid has the opportunity of transfusing into the surrounding air, and it is much lower in such operations than in those in which there is no such opportunity for the carbon dioxid to pass off into the air. While it is true that rebreathing in the administration of nitrous oxid reduces very materially its cost, I am quite sure that it is not the proper reason to give, and I am quite sure that the men who have been primarily engaged in the production and the promotion of nitrous oxid anesthesia with rebreathing have not placed their work on that basis.

Prof. Yandell Henderson, New Haven, Conn.: I did not say what Dr. Coburn thinks I did. What I said was that the method of rebreathing started as a question of cost. I would say that we have no exact measure of rebreathing in the individual patient, and until we have some clinical measure of rebreathing it is not on an exact basis.

Dr. Robert H. Ferguson, East Orange, N. J.: While I use the open drop method almost exclusively in my work I now merely call attention to my belief that about 92 per cent. of all the ether anesthesias in the United States are by the open drop method. This opinion is formed from a careful scrutiny of all the statistics I can get together with personal observations made in many hospitals in over 75 per cent. of the states of the Union. Further, I believe that when anesthesias by this method have not been so good as were desired, the failure has been due to unskilful administration, perhaps aided by an improperly arranged apparatus, rather than to the method itself. A point, then, I wish to make is this: that instead of endeavoring to bring out new apparatus and multiplying methods we ought to concentrate our attention on one simple procedure, such as the open drop method, and perfect it. After its range of usefulness is determined it will be right to study exhaustively another method, if the first is unsatisfactory. Experimentation in anesthesia ought, however, to be of the most conservative kind, since the safety and comfort of the patient is involved. To a mind impressed with such a necessity, the little advance made in a simple method of administering ether during the last twenty-five years is a matter of regret.

As regards anesthetic statistics, we should be very patient, not content with a small number, with those of one locality only or with any of a doubtful or limited value. Dr. Cotton has suggested that the majority of our anesthetic statistics are of small value. I believe that such is the fact chiefly because they are not complete. As an illustration let me say that it has been my duty, from time to time, to investigate so-called anesthetic deaths in various parts of the United States. Often when my attention has been called to one death I have found nine or ten in that vicinity. Again, while on the train, coming to this meeting, a surgeon told me that the hospital with which he was connected averaged five chloroform deaths a year although his patients always had ether. I could give other illustrations. Now practically none of these deaths are reported in print. Some were mentioned at meetings of local societies but were you or I collecting data for statistics of anesthetic deaths none of these cases would be available. I think these facts are strikingly conclusive of the untrustworthiness of our anesthetic statistics. I wish that every hospital and every surgeon would realize the importance of putting on permanent available record every death, directly or indirectly due to the anesthetic, together with full details of the case.

Dr. T. D. Buchanan, New York: I want to report without pride two unsuccessful cases, merely as a warning and possibly a help to some of you as surgeons or anesthetists, in diagnosing the same thing that I ran across. After fifteen years of specializing in anesthesia in New York City without any deaths, I came across two cases in two weeks and lost both patients, one under ether and one under gas and oxygen. Both patients had enormous fibroid tumors of the uterus; both were pretty well exsanguinated by frequent hemorrhages, and both died very suddenly in the midst of the operation. Now statistics with regard to deaths on the table are very hard to get. The causes of the deaths of this sort in the hospitals with which I have been connected were hard to find. Each time that I went to investigate one the surgeon would say that it was an anesthetic death and the anesthetist would say that it was caused by shock. That is why we cannot get statistics. In my own cases of fibroid the deaths were due solely to the anesthetic I make this excuse for myself, however that in a number of fibroid cases there is fibroid degeneration, not only of the uterus, but of other parts and tissues of the body, and frequently of the heart There are numerous authorities for that statement, and I believe that this is what I encountered I have known other deaths to occur following fibroid operations, ten or twelve hours afterward, but not on the table The first case might have been due to my not paying attention to the anesthetic, but the second surely could not have been, because I had just had a warning a week before from the other fibroid case, and was watching every second The second death, as I have said, occurred under nitrous oxid and oxygen We should have a very wholesome respect for these cases and not keep the patients in the Trendelenburg position longer than necessary, and the anesthetist and surgeon should avoid throwing even the slightest strain on the heart

Dr A F Erdmann Brooklyn, N Y I take this opportunity of thanking some whose names I cannot recall for sending to me the sample anesthetic charts for the society and other libraries I have a collection of nearly a hundred, some of them are certainly queer Three or four are very long, a number are very short, some contain only few details, others have space for numerous data, most of them omit important matter, so valuable that I cannot see of what use they really are As a matter of fact, few charts are properly kept, mainly, I believe, because the intern realizes that pulse rate, amount of anesthetic used and length of time of operation tell practically nothing of the course of his labor May I suggest that we go over our charts again to see if there is not something to add to them that will make them more interesting to yourself or to some one else, and which will give them a value for those who like Dr Gwathmey are endeavoring to gain knowledge of this subject for the common good? Until we use good charts and have them kept conscientiously we cannot expect to be able to gather reliable statistics

Dr F R Widdowson, Philadelphia Dr Buchanan, in his discussion, brought up the subject of statistics I suppose, if he has had experience in looking up statistics of this character in a hospital, he has found them to be of little value, owing to the way in which these records are usually kept I think that the reason why Dr Gwathmey failed to get reports from many hospitals was their inability to render a report of value from the imperfect records If a hospital does not have a form, as Dr Erdmann has just said, on which the anesthetist can record the data concerning the administration of an anesthetic, the records regarding anesthesia will be very meager For those who teach and have charge of the anesthetic work in hospitals, the first thing is to have a "form" on which data are collected systematically If the administrator knows he has to make a record of these things on a chart, he will attend to his work in a more systematic manner, think of the different points, and derive more benefit therefrom I would say to the surgeons and anesthetists here One of the best things you can do is to have an official chart made for your hospital when you return If you have one, you can improve on it getting additional data Then when Dr Gwathmey or some other anesthetist tries to get statistics he will be able to get them satisfactory to himself and to you, and it will be a pleasure, for the hospital asked, to give them

Dr Frank W Pinneo, Newark, N J There are four principal elements necessary for the success of insufflation anesthesia, which the report of the Committee on Anesthesia recognizes, that is, first, the warming of the vapor in the insufflation apparatus The three other factors are maintenance of a steady air pressure a cock on the apparatus to determine and govern the delivery of vapor to the patient and a catch bottle to make it impossible for any liquid ether to be carried over to the patient We ought not to think nitrous oxid and oxygen useless because some ether has to be added and where such an exponent of it appreciates the little ether added it helps to broaden the field for nitrous oxid and multiply its users Dr Gwathmey also has pointed out the value of nitrous oxid, which is, as Hewitt said, 'the safest anesthetic known" There is a contra indication to its use in children under 5 years of age, but here straight ether is usually good, or, in competent hands, with caution, we may be able to use chloroform for induction (never after an initial period of "ether excitement')

Dr. F K Ream, Chicago I have been administering nitrous oxid and oxygen for over twenty years for the extraction of teeth This particular work led me to engage in hospital practice, and my work is largely limited to that now I have so completely covered the ground of the use of the various methods that I am really apparatus poor having purchased most of the outfits on the market, my experience has led me to the selection of two methods My method of choice is the Teter, using large nitrous oxid and oxygen tanks with continuous, uniform pressure, making it possible to obtain intrapulmonary pressure, as recommended by Dr Teter I cannot with any other method on the market obtain relaxation and control my patients without ether, as I can with the intrapulmonary pressure I consider all other methods substitutes I think that Dr Teter's methods and research have done more to eliminate and limit the use of chloroform and ether than those of any living member of the profession

I have recently had a series of cases in which I used Dr Coburn's apparatus for a mixed anesthetic and rebreathing In some of these, I did not use any ether whatever, and obtained splendid relaxation In cases in which that is possible, the patients, I believe, must be susceptible to anesthesia in order to bring about that condition but I am satisfied that I can obtain very much more relaxation from nitrous oxid and oxygen under pressure

Dr J W Heim, Louisville I disagree with the man who recommended the chloroform ether sequence for children to whom we do not wish to give chloroform straight. I think that is the most dangerous form of anesthesia If in giving an anesthetic the beginning is the most dangerous, why should we use chloroform, which is the most dangerous anesthetic at the most dangerous time? I would rather induce the anesthesia with ether

Dr W S Bainbridge, New York First, the early mortality from spinal anesthesia cannot, I think, be attributed to cocain but to the excessive dosage of cocain employed and the wrong technic From my own experience, I have learned that stovain and tropacocain are the spinal anesthetics of choice Still, cocain has been uniformly of value in my cases The only new thing about Jonnesco's method was that he put strychnin with his analgesic drug into the cord Stovain had been used before, the high puncture was not new strychnin had been used by others In 1901, I was personally employing strychnin under the skin to offset any bad effects of cocain in the subarachnoid injection

By using cocain low in the cord, I have been able to do operations on the top of the head and have had a number of cases of total analgesia I thoroughly believe that there is such a thing as preanesthetic anticipatory shock, and the person who says to a patient about to take any anesthetic Look what is going to happen," is giving him a certain amount of shock, with which the anesthetic has no right to be saddled Whenever possible, the mind as well as other organs of the patient should be properly prepared for any anesthesia I think that it is a safeguard to the patient for the surgeon to watch what he is doing There is likely to be less shock from unnecessary handling of the tissues when the patient is conscious

I have had children as young as three months sucking the bottle while the operation for incarcerated hernia was going on and only stopping their sucking of the bottle with a good, ravenous appetite, to give a cough indicating the general bronchitis that was present Waugh and Lane assert that the use of spinal anesthesia in acute abdominal conditions in children reduced the mortality about 20 per cent

Dr. Charles K Teter Cleveland What is the prevailing impurity usually found in nitrous oxid? I have had reported to me within a month two fatal cases in which nitrous oxid and oxygen were used death being due to impurities There are such peculiar symptoms manifested in such cases that the cause cannot be overlooked The patients have a very *peculiar greenish red color, and the blood seems almost* of a rusty hue Dr Clifford U Collins, of Peoria, Ill, reported a fatal case with these symptoms within the last month I have had two cases in which these symptoms arose and in both I found that my gases were impure I did not have the opportunity to have the gas analyzed, in order to find out what particular impurity produced the condition The patients were quite sick for a day or two but recovered I think that the impurity was probably nitric oxid

It has been said lately that all that was necessary to make the present nitrous oxid and oxygen apparatus an automobile was the addition of a carburator If nitrous oxid is the agent used to induce and maintain anesthesia and not as a makebelieve, a more or less complicated apparatus is essential At present it may be admitted that in the way nitrous oxid is administered by a good many people it is not the anesthetic They are really using the closed method of ether giving 3 or 4 ounces of ether in an hour but calling it nitrous oxid anesthesia It requires only an inhaler and a bag and a couple of cylinders to do this but if one depends on nitrous oxid and oxygen, only using the oxygen to eliminate the asphyxia, one must have more apparatus and also some sense to know how to employ it I have seen some men give anesthetics who, if they had to pass as stringent an examination in regard to the subject of anesthesia as a chauffeur has to pass in his examination, would fail

One must use common sense in employing positive pressure If it is used to such an extent that stress is thrown on the respiratory mechanism, one is using too much If there is strain, one should change the pressure There should be no strain In the average case, if one uses 6 to 8 mm of mercury pressure it will not hamper respiration in the least If this is too much, the pressure should be released. The reducing of pressure in a cylinder is important in securing a perfectly *even flow of the gases*

DR. A H MILLER, Providence, R. I It is a fact that there have been no reliable statistics of the mortality from anesthetics available, but I do not believe that this should be I believe that we can get valuable statistics of the mortality from anesthetics In the first place we must separate the deaths that occur as the result entirely of the anesthetics from those in which the anesthetic contributed to the fatal result and from those in which it had no effect *in producing the mortality*

DR. JAMES T GWATHMEY New York The statistics, as given this afternoon are certainly reliable, and more reliable than any heretofore taken Indeed, they are more reliable and of more consequence to us for they represent the results of statistics as given in the United States to day Dr Cotton, in his discussion, stated that he doubted their value, because he knew that many unreported deaths occurred under anesthesia, and also that postoperative deaths are probably not reported in these statistics It is a question whether any postoperative deaths are reported yet we know that they do occur after all anesthetics In the last month, I know of a case (a laparotomy) in which a local anesthetic was used The operation was successful, and a large tumor was removed the patient died a few days afterward from pneumonia The question is so complicated that if we go into the matter of collecting reports of deaths after operation it is doubtful whether even if we had the statistics of all postoperative deaths they would be as reliable as the statistics we have that can be compared with similar ones already in existence We know that anesthetic statistics are recorded in but few hospitals of America to day The fact that I sent out circulars to the hospitals started many of them in the work of compiling statistics and I would suggest that if it is known that statistics are being asked for they will be more careful in the future

Anesthetics are in a state of evolution There is no one accepted method of anesthesia As to the question of whether local spinal, morphin or pulmonary anesthesia alone or in combination is the best method, no one can say positively Therefore I should like anyone who is connected with a hospital that has not given statistics, to assist me by asking for a circular to fill in This report will be the first that has been made of reliable statistics in America

PROF CHARLES BASKERVILLE, New York As to the different prices of ethers, I would say that I make it a rule to pass on the quality, without inquiring about the price It is immaterial what the price is That involves a problem of manufacture which is not generally known, outside of what I have presented in the paper Some manufacturers make one grade of ether—anesthetic ether, they call it Some make just ether”—chemically pure ether (which is infinitely purer than the anesthetic ether), anesthetic ether, commercial ether Ether may be thus of three kinds and they may all be made in one way You know the class of labor that many manufacturers employ, and when they get to the packing, there is danger of mixing these ethers I have had some cases of that kind It might have been an accident, but it happened Some manufacturers of ether prepare only one grade anesthetic ether, and some manufacturers who make the different grades can afford to sell commercial ether at a low price They then rectify a little of that, so as to get just enough to keep their trade in the anesthetic grade It is a perfectly good ether, but if nothing was paid for it, they would lose nothing Every cent that they get for that is net profit. It costs them nothing to produce it

The truth is that when we gather statistics we do so for two purposes One of these is the matter of curiosity That is all statistics show in one way The other object is to learn something, and what we want to learn is how to get over the troubles that we have been having I am convinced that each drug has its specific action and the processes that go on in the human body are the same as those that we control in the laboratory, and that is the whole field of medicine If we can learn to control the different reactions we have the problem solved That is one thing about getting an anesthetic into the system Of course, I realize that it is dangerous for a chemist to trespass in a field of that kind, but I shall be out of town soon The anesthetic ought to be sent in approximately at the temperature of the body It should also be sent in approximately at normal humidity, and both of these have been accomplished by means of vapor anesthesia, whether nitrous oxid or other kinds if passed through water

An improvement on Dr Gwathmey's method is that of Dr Davis which consists in saturating vapor with water and warming it afterward, so that it enters with a degree of humidity of 60 or 70 per cent

ANESTHESIA BY PHARYNGEAL INSUFFLATION *

FRANK WILCOX PINNEO, M D
NEWARK, N J

The ideal anesthesia includes four factors (1) an induction short, tranquil and not unpleasant to the patient, (2) a maintenance, surgical, even, featureless and so absolutely under control that it is but just deep enough each minute for the existing purpose, (3) a recovery prompt and complete (4) after-effects, *nil* i e without symptoms immediate or remote, in any organ, alimentary, respiratory circulatory or excretory It is true of every known method that as it approaches this ideal in some respects it recedes in some other, hence the need for adapting the anesthetic and its method of administration to the individual case, choosing the best combination of results attainable

---

* Read in the Section on Diseases of Children of the American *Medical Association at the Sixty-Third Annual Session* held at Atlantic City June 1912

In the surgery of childhood — not a new subject but bound to receive more special attention — we are confronted, in anesthetics, with the pediatric problem of administering to an organism, embryonal in some degree, potent drugs to which it is peculiarly susceptible Hughes[1] points out in this connection that age and body-weight are as important as in feeding or medication The same authority shows the fault of a "smothering" induction, that the workable limits of a safe maintenance are very narrow that under 5 years of age any deprivation of oxygen is badly borne that liability to surgical shock increases, not diminishes with deepening anesthesia, and that detection of shock is especially important and not easy Kelley[2] of Cleveland, says that prolonged operations are bad for children and all can confirm this who have watched the vitality wane in one who may have gone through the first half hour very well Kelley also emphasizes the need of gentleness in manipulation of the delicate tissues of a child quoting Bloodgood[3] that 'rough handling of tissues and hemorrhage" are most productive of shock

UNIFORM MAINTENANCE OF ANESTHESIA

In the evolution of surgical anesthesia since its beginning with Long 1842 Wells 1844 and Morton 1846 the present age demands not so much discovery of new anesthetics as refinement of methods and greater accuracy in the use of the materials we have But this — to be practical and universal — must be accomplished without elaborate apparatus The report of the Anesthesia Commission of the American Medical Association,[4] just made public in the Handbook of the House of Delegates of this Association says "Recent developments in this field afford ground for the hope that we are to-day at the beginning of an epoch of progress in anesthesia unequaled since its original discovery and introduction The need is for an anesthesia featureless, safe, surgical, yet not more profound than immediately necessary The maintenance of this state is our chief concern, and is difficult particularly in operations about the throat and face where anesthetist and surgeon both need the same field Kocher, in his "Operative Surgery, says, "Even careful surgeons are still confronted with the great difficulty of maintaining the right degree of narcosis during a prolonged operation' The above-mentioned report of the Anesthesia Commission[5] also says

> As regards ether the two points to be emphasized especially are that *anesthesia* should always be induced quickly and that throughout its entire duration it should be as nearly uniform as possible It is not the anesthetist who at all times maintains uniformly deep anesthesia whose patient stops breathing This accident comes particularly to those who administer so irregularly that the patient at times comes nearly out of anesthesia and again is plunged into profound narcosis Anesthesia is good in proportion as it is uniform Offenses against this principle occur most frequently in adenoid and tonsil operations When the death of the patient (usually a child) results, it is assigned either to heart disease' or to an 'unrecognized condition of status lymphaticus It is probable that in most cases these deaths are merely the natural result of intermittent anesthesia and of the increased susceptibility induced by fear Under the ordinary methods the anesthetist and the operator are alternately in control of the patient's nose and mouth

Packard[6] has compiled a list of twenty-nine deaths from the anesthetic in tonsillectomy twenty-six of them being from chloroform none from ether That this especially concerns children is seen in that twenty-two of twenty eight patients were 12 years or under, five between 13 and 16, and one 20 years That intermittent anesthesia is very deleterious even deadly is reported by Yandell Henderson[7] with confirmation by Carrel in animal operations showing that renewal of the anesthetic after partial recovery is fraught with much danger His comment[8] on the case reported (death in stage of ether excitement under tonsillectomy) is

> The reason that 'unsuspected status lymphaticus" is so often invoked after tonsil operations lies less in any connection of the tonsils with the thymus than in the fact that ether is administered intermittently in such operations and the subject comes part way out of anesthesia

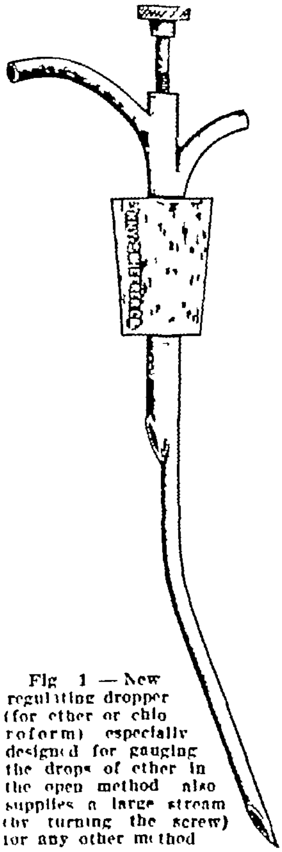

Fig 1 — New regulating dropper (for ether or chloroform) especially designed for gauging the drops of ether in the open method also supplies a large stream (by turning the screw) for any other method

He thinks that "status lymphaticus' has been made to bear an unreasonable burden of deaths from unexplained causes and adds

> If anesthetists will only realize that this (interrupting the administration of ether) is *a procedure which above all others should be shunned* the number of cases of so called 'status lymphaticus" under anesthesia will I believe show a sudden and marked decrease

The problems are not solved in simply choosing the method In the preliminary report of the Anesthesia Commission of the American Medical Association Cunningham and Anderson[9] giving a summary on the closed method of ether, cite as a disadvantage that the uneven administration (due to intermittent application) trespasses on the safety limit and predisposes to shock

But in adopting the open method[10] another difficulty confronts us The same investigators[9] found this so characterized by refrigeration the evaporation of ether on inhalation extracting so much heat from the lungs (for exhalations are warmed) that 'if refrigeration is a factor in postanesthetic pulmonary complications or shock the open or drop method must head the list as it extracts most heat from the patient The semi open *method, as with the Allis inhaler* is a compromise between the closed and open method standing nearer one or the other according to the freedom of air admitted or amount of rebreathing allowed That it must have great merit is shown by the great extent of its use and by the tendency I observe, in even those who think they are using the open method to withhold partially the patient's exhalations by a surrounding towel or even a partial impervious cover over the mask. Again how many do not drop the ether on but pour it more or less intermittently? If the drop method is chosen the ether should be administered by perfectly regular drops.

A REGULATING DROPPER

To facilitate this I have designed a regulating dropper which may be set at any desired rapidity of drop or stream, is inexpensive and easily inserted in any cork. The best mask has rather than a thin layer of stockinette, enough layers of gauze, with coarse mesh to hold some vaporized ether (yet not enough to prevent breathing through it). This diminishes refrigeration and improves the volatilizing of the ether. I am confirmed in my opinion of the value of this by the judgment, in animal operations, of so accurate an observer as Alexis Carrel,[11] who says "I found that my animals lasted much better if the mask used to etherize had a large dead space so as to involve a considerable amount of rebreathing."

RECTAL AND SPINAL ANESTHESIA

For operations about the head, rectal etherization has been developed,[12] but its field must be very limited and dependent on a skilled anesthetist and careful preliminary preparation of the rectum. It adds rather than removes difficulties. Spinal anesthesia[13] has its field, but the untoward effects during operation and the aftereffects, according to Freeman Allen,[14] are such that, in spite of any indications for it in given cases, it can never wholly replace inhalation anesthesia with its adaptability in depth and control of anesthesia, to the age of patient and kind of operation—an adaptability especially promoted by the use of such means as I propose.

NITROUS OXID-ETHER SEQUENCE

In the search to combine the advantages of different anesthetics, the present age has come, happily, to the use of nitrous oxid preliminary to ether. Such a sequence must be sharply distinguished from mixed anesthetics such as the A. C. E. mixture, with their uncertainty and danger. Nitrous oxid, especially with oxygen, is most safe. In sequence with ether as by Gwathmey's apparatus it affords the advantages for induction and, if the ether following be administered conveniently for head operations we approach our ideal in maintenance as well as induction. Sequences have come to stay, and statistics prove they are safe. The Pennsylvania Hospital[15] in 11,167 anesthesias had eight deaths none under sequences but all among the 2,391 straight anesthesias three under ether five under ethyl chlorid. Nitrous oxid and oxygen followed by ether has much to commend it for with these under instant control by proper apparatus as Teter's almost any indication may be met, the ether being as Crile[16] has shown, an important factor in the administration. The disadvantages he enumerates include the apparatus and experience necessary, the venous congestion and incomplete muscular relaxation to which might be added the customary hypodermatic of morphin which in children is contraindicated. In this connection Crile cites a requirement in the administrator, which must appeal to the judgment of everyone having at heart successful anesthesia namely a certain personal equipment which affords "the keenest perception of the precise condition of the patient at every moment, i. e., the anesthetist must be a most delicate human recording apparatus."

PRELIMINARY MORPHIN

Bevan[17] and Herb[18] contend against the use, as a routine, of preliminary hypodermatics of morphin or scopolamin. This question has two scientific aspects: (1) that by its action on the cerebrum, morphin tends to block harmful sensations and, also, that it quiets the respiratory center, thus diminishing danger from acapnia produced by hyperpnea either voluntary or due to ether excitement. (2) that this very action toward paralysis of respiration removes one of the best safeguards of life, sensitiveness to the stimulation of carbon dioxid (vital, as Henderson[19] has shown) and of ether and hinders excretion and prompt recovery afterward. Alexis Carrel,[11] at the Rockefeller Institute, says, "I do not give morphin. I use only ether." For our present subject this applies only in so far as it concerns children and the severity and duration of the operation with its need for fortifying the patient against harmful sensations. Crile[20] has well pointed out that there are at work on the nervous system noxious influences which anesthesia does not prevent and suggests means for producing a state of anoci-association (absence of harmful associations). This has its chief application in the handicapped patient, i. e., one whose vitality is seriously impaired, as by infections or severe injury. In the case of children fear is easily overcome by judicious use of our knowledge that they have no natural fear, but that it is learned only by experience.

ANESTHETIST AND OPERATOR IN SAME FIELD

Considering the aims toward the ideal anesthesia which the above facts and opinions suggest and applying them for operations in and about the mouth or head, we find the following provisions indispensable:

1. After induction of anesthesia the anesthetic must be uninterrupted and capable of administration to any degree the exigencies of the case demand.
2. The operator and administrator must have equal access to the respiratory tract, each without interrupting the other.
3. Sufficient anesthetic must be admitted by either mouth or nostrils alone.
4. The ether vapor must be warmed, and the extraction of heat by the rapid evaporation of ether must be met by the constant supply of an equal number of calories.
5. Finally the method must be safe as against the possibility of pumping any liquid to the patient, and simple,[17] so that anyone, qualified for any anesthetizing, may use it with only the ordinary precautions.

The Junker inhaler for chloroform, which was brought out about 1860, consisted of a small 1-ounce bottle with inlet tube to the bottom for air and outlet tube from the top to the patient. Many deaths resulted from its use the files of the *British Medical Journal* contain many compiled reports Hewitt improved it with a double tube, to obviate the possibility of connections getting reversed and liquid chloroform being pumped to the patient Kocher in his "Operative Surgery" said "Rose declares that the introduction of Junker's apparatus is the most important advance that has been made in the matter of anesthetics"

THE PRESENT METHOD OF PHARYNGEAL INSUFFLATION

I have used the method now described in some form for three or four years It was presented to the New Jersey State Pediatric Society in June, 1911[21] It is designed for ether, but I could recommend it for chloroform, did I believe in chloroform by insufflation as I do ardently in ether The apparatus consists of a double rubber bulb maintaining air under a little pressure, which flows, controlled by a cock, through ether in one bottle, then into a second bottle (empty) and thence by tube to the patient's oropharynx or nasopharynx, as may be chosen The bottles hang in a water-bath heated by an incandescent lamp beneath A thermometer is kept in the water After induction is accomplished, preferably with nitrous oxid, anesthesia is *maintained with ether* It accomplishes the following objects (1) the air-pressure being constant (70 mm of mercury is the maximum with hand-bulb), the administration is even and (2) its rapidity is controlled by means of the stop cock, (3) the ether in the first bottle is warmed and the etherized air passing from it is kept warm in the second bottle, which also serves (4) to catch any ether condensed in the tube beyond besides absolutely preventing any being pumped from the first bottle over to the patient (5) a temperature of 98 F is *maintained in the water by the incandescent* lamp the calculation being that the ordinary and convenient 16 candle-power lamp will in the copper vessel replace the loss from the rapid evaporation of ether (but without this lamp attachment simply drawing off some water, by the water-cock and replacing with warm answers as well), (6) *there is flexibility in choice of* three methods of delivery to patient, by metal tube in angle of mouth, or pair of Lumbard s glass tubes in nostrils or pair of rubber catheters graduated introduced to level of the soft palate, (7) operator and administrator are mutually independent in the same field (8) the apparatus is simple, easily kept in perfect order, inexpensive portable usable by any anesthetist anywhere

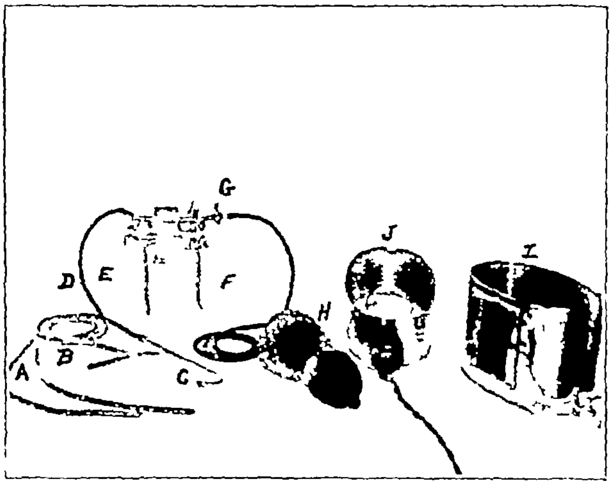

Fig 2—Insufflation apparatus for ether anesthesia (A) two nasal catheters (graduated) or (B) two nasal glass tubes or (C) a metal tube (shaped for angle of mouth) are attached to (D) delivery tube coming from (E) empty bottle connected with (F) ether bottle (graduated in grains also liquid ounces) (G) Cock governing the air pumped from (H) double bulb (J) Water bath in which the bottles are suspended (I) Base (containing incandescent lamp) on which the water bath fits but which in lack of electricity may be dispensed with and the cooling water replaced with warm by hand

I emphasize the value of warming the ether a facility not hitherto appreciated except by very few writers recently, notably Gwathmey[22]

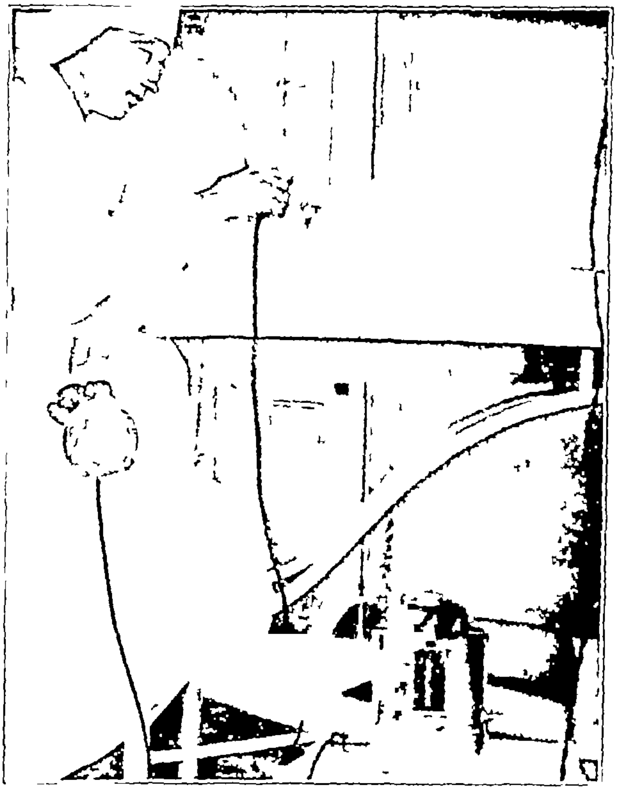

Fig 3 —Ether anesthesia by pharyngeal insufflation Ready for operation The apparatus is entirely out of the way only a metal tube in mouth of the patient being in the field of operation The air pressure is steady Administration is uniform (determined by cock) The ether vapor is warm No liquid ether can reach the patient

Cunningham and Anderson[19] state that with the open method "experiments have demonstrated that in a room at 80 F 2 1 per cent ether vapor reduces the inhalations to 30 F and 5 4 per cent ether vapor reduces them to ° F thus causing a loss of about 21 000 calories of body heat for every ounce of ether used Even this does not fully show the conditions in practice as I have *found by thermometer in the gauze the temperature to* be 0 F during operation Contrast that method with insufflation in which the vapor delivered into the pharynx of the patient is 87 F and may be maintained at 84 F under any rate of flow

INTRATRACHEAL INSUFFLATION

In the discovery of intratracheal insufflation Dr Meltzer[23] with Dr Auer has done the world great service When automatic respiration has ceased to able to substitute, surely and safely, artificial respiration, or when operation necessitates opening the thoracic cavity, to be able to give an anesthetic safely and smoothly in the absence of any automatic breathing, or even excursion of the lung, is a discovery which marks a new era. The courtesy of Drs. Meltzer and Auer in personal demonstrations at the Rockefeller Institute is appreciated and cordially acknowledged. It is thrilling to see an animal with both lungs exposed to atmospheric pressure anesthetized and oxygenated so well that the lungs are pink and full and the skin and mucous membranes looking as in healthy sleep. Especially interesting to our topic is Dr. Meltzer's latest publication,[21] of artificial respiration by pharyngeal insufflation. It could be easily applied with my apparatus *adding a manometer* and provision for substituting instantly oxygen or air in place of anesthetic and thus equip the operator with resources for treating respiratory embarrassment from any cause. This is a preliminary note on some suggested experimental study (Fig. 4).

[23] Meltzer Intratracheal Insufflation Med [illegible] March 19 1910

ADVANTAGES

My method, while designed chiefly for throat and head operations to facilitate surgeon and anesthetist working in the same field, maintains an anesthesia so dry, even and controlled, whether shallow or deep, that I have come to use it for all kinds of operations, including the following: tonsils and adenoids, brain tumors (positions supine and prone), cervical adenitis, cancers of tongue and jaw, lymphangioma of tongue, appendicitis, hernia, meningitis (draining the fourth ventricle), prolonged dental operations, hip dislocations, osteomyelitis, club-feet, knock-knees, mastoiditis, pelvic operations, nephrectomy. The warm evenly supplied ether vapor seems to find so easy entrance through the pulmonary alveoli that some of the common embarrassments of other methods, such as wet anesthesia when crowding the ether, are entirely absent (and no new ones occur!) (Fig. 5).

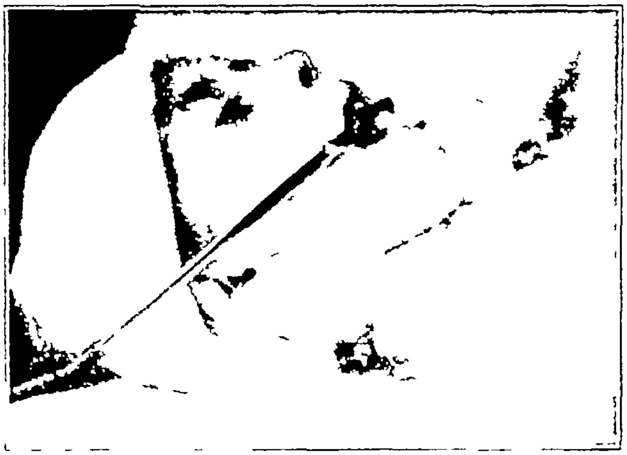

Fig. 4.—The mouth tube in position delivering a steady warm ether vapor. Both anesthetist and operator are independent though in the same field.

A recent discovery was the unexpected ability to anesthetize an alcoholic man to whom ether was like alcohol; increasing the dose by ordinary mask therefore would simply produce a vicious circle of cyanosis and muscular rebellion. He yielded on introduction of the mouth-tube in one or two minutes smoothly with good color and dry throat, and he had had no preliminary hypodermatic of any drug whatever! That the success in such a case may be life-saving against a fatal, prolonged period of ether excitement is shown in the case mentioned by Henderson.[19]

FOUR ESSENTIAL ELEMENTS

In conclusion recognition is urged that the following factors are all of them essential in this method of anesthesia by pharyngeal insufflation: (1) steady air-pressure (whether by hand-bulb or foot-bellows); (2) a cock, fixing, at the anesthetist's discretion, the delivery of vapor to the patient, and maintaining it evenly; (3) a catch-bottle interposed between the ether-container and the delivery tube; (4) a heating system which will maintain evenness of temperature.

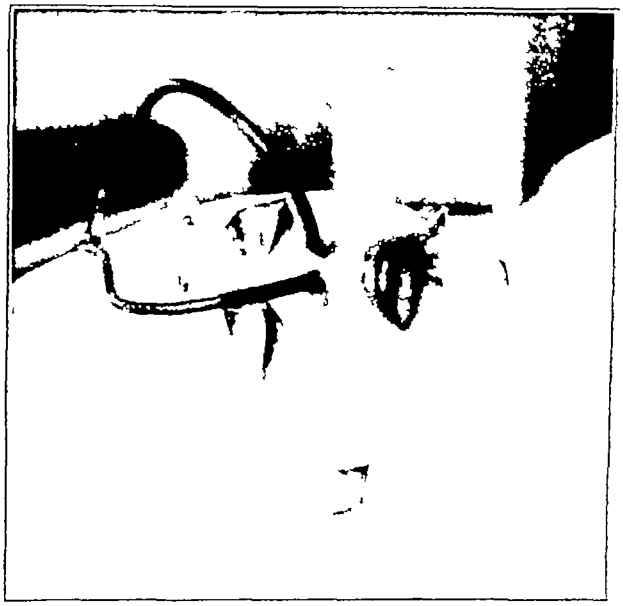

Fig. 5.—The nasal catheters in use. The mouth tube is also shown though usually unnecessary in addition.

Without all of these the method would be fundamentally lacking; with them, even in different form, it would have the essential elements.

199 Garside Street.

ABSTRACT OF DISCUSSION

Dr. James T. Gwathmey, New York: It has been stated that it is impossible to heat ether vapor. I have made a number of elaborate experiments to prove not only that vapor can be heated but also that it can be kept at a uniform temperature as long as required (*New York Med. Jour.*, June 1, 1912). There is nothing in the world that cannot be heated. To say that one cannot heat ether vapor is to violate every law of physics as we know them to-day. Especially is heat desirable in the administration of anesthetics to children, because loss of heat is one reason for shock. You all know how rapidly a child parts with heat under an anesthetic. Every precaution should be taken to avoid this.

Sequence in anesthetization has come to stay. Dr. Woolsey has proved that by having the child inhale the essence of orange by the closed method and following with ether the cyanosis that sometimes accompanies the administration of the "gas-ether" sequence is not produced. With little children especially *I do not believe in the use of chloroform* except in an exceedingly hot climate; even then I do not want to take the responsibility of saying that we should use chloroform throughout with the clinical results of the effects of chloroform before us. Nevertheless, I think that is one of the best methods of introducing the anesthetic to the child. The chloroform

[21] Meltzer, S. J.: Pharyngeal Insufflation: A Simple Method of Artificial Respiration, The Journal A. M. A., May 11, 1912, p. 1413.

While I would not be misunderstood as claiming that every "surgical child" should be examined by a pediatrist, yet it remains a fact that the proposition is often a twofold one and the attempt of the surgeon to cope with a surgical procedure with which he is entirely familiar in a being with whom he is unfamiliar is often as disastrous as would be the attempt of the pediatrist to undertake a surgical procedure with which he is unfamiliar in a being with whom he is entirely familiar.

There are so many modifications of the purely surgical consideration that are offered by the changing response of children at different periods and particularly modifications which have their genesis in underlying nutritional states, which few but the trained pediatrist can understand and cope with, that it is unfortunate that the operative skill and courage of the surgeon is not more often coupled with the judgment and experience of the pediatrist. Such counsel would give the child and the surgeon their best chances.

A thorough examination is in practically every instance necessary to establish an accurate diagnosis. For the reason that the examination of young children is commonly incomplete, the diagnosis is often inaccurate and not complete enough to insure a full measure of success. This diagnostic inaccuracy is fostered many times by a knowledge that has been acquired through unreliable sources. In a few instances the accurate knowledge is so consciously insufficient that psychologic factors are allowed to enter. Take as a common example, the subject of acute appendicitis in children; its importance is so emphasized and it is so constantly the topic of discussion that it is immediately thought of when abdominal pain occurs in children. And yet abdominal pain is commonly a minor feature of acute appendicitis. Or again, take meningitis: if varied nervous phenomena are present which are not readily understood, meningitis is often diagnosed when it does not exist. My consulting records show that it is rare to find a diagnosis of acute appendicitis or meningitis overlooked in childhood, but on the other hand it is common to find them assigned as the cause of symptoms when they do not actually exist.

Generally stated, an accurate and a complete diagnosis is essential to the institution of adequate treatment, but this is not invariably so. For example, I have observed several instances in which, when viewed from the purely surgical point of view, an accurate diagnosis was practically impossible without exploratory incision or other surgical procedure. And yet there were other factors present which would markedly influence the end results.

If such factors are ignored or reduced to a minor consideration, there is immediately introduced into the problem an uncertainty which does not conserve the morbidity or mortality of postoperative convalescence. To appreciate what the end-results will be in any given case requires very often a close consideration of facts that at first seem to have little or no bearing on the disease or injury, but which will force themselves into the problem just as soon as the depressing effects of any surgical procedure are brought into play.

Not infrequently we are asked, "Can the child stand the operation?" Too often it is dismissed thoughtlessly and the child suffers a serious injustice because a surgical procedure that promises a result in the first instance is delayed until in a later stage it is accompanied by added difficulties and does not restore the child's full efficiency. Such a question should be answered by another: "Can we in this particular case adjust our surgical technic to meet all of the conditions presented by this particular child?" The claim is constantly made that there is a too ready recourse to surgery in childhood, and to some extent this may be true, but it is my opinion, based on several years of observation, that operative timidity and procrastination are often the cause of operative insufficiency, and that our greatest danger in childhood is in good surgery wrongly applied.

The final results of a skilfully executed surgical procedure have not infrequently been compromised or jeopardized by overinterested, underinterested or inadequately warned assistants.

It is assumed that their selection as assistants is proof of their ability, but irrespective of this, all three classes influence the final outcome of a surgical procedure in childhood in exactly the same way, but from different motives. The overinterested assistant is more alive to the technic of the operator than he is to the best interests of the child; the underinterested assistant looks on the procedure as just so much necessary work to be done and is not in full harmony with the operator's scientific interest; the inadequately warned but trained assistant simply does not know. Each in his own way influences the end-result, contributing not so much to the mortality as to the morbidity, because each contributes more or less to the production of shock.

Now what factors in the production of shock does the assistant have more or less under his control?

They are mainly two: hemorrhage and injury. It must be recognized that whether the blood-pressure is directly reduced or not, the mere loss of blood is sufficient in itself to cause shock in children and the degree is influenced by the rapidity of that loss. It is not sufficient, therefore, simply to prevent the loss of blood, but the assistant must be zealous in immediate attention to all bleeding surfaces and, whenever practical, a vessel should be secured before its division.

Injury that conduces to shock in childhood is not only that made necessary by the operation, but in many instances, is the result of pulling or dragging on the tissues and particularly on those tissues which are directly connected with some organ. It is as commonly the unnecessary injury done by the assistant as the necessary injury by the operator that adds to the degree of shock in young children.

In far too many instances it has been the policy to designate the least experienced intern as the anesthetist and, without going into a discussion of the matter, it is sufficient to state that such a procedure is unwise and in no way conserves the best interests of the patient or the operator and is a most certain way of adding to postoperative morbidity and mortality and of prolonging convalescence.

Too often the role of the anesthetist has been assumed as being necessary but unimportant. And the anesthetist himself has largely contributed to this general opinion by assuming the position of a necessary adjunct to a surgical procedure rather than realizing and making others realize that he is actually and largely a direct contributor to the success or failure of the procedure. Too often he asks, "What anesthetic shall we use?" Too often he without protest obeys the command to "push the anesthetic." Too often he accepts the relationship of an inferior when he should be an equal. Who is better able to decide what anesthetic to use and when to push it or withhold it, the trained anesthetist or the surgeon? Surgeons should be more acute generally in realizing that the anesthetist is either a constant danger during a surgical procedure, a necessary adjunct who requires constant watching and suggestion, or is a most valued co-worker according to the thoroughness of his training and experience. And, if in the latter class, it is the operator's duty outwardly to recognize within and without the operating-room the true value of his service and surround his position with the dignity and esteem which it rightly deserves. The danger of an anesthetic in young children is not so much from the asphyxial element as from the toxic, and therefore the preservation of normal functioning should be left to the anesthetist rather than to the operator.

In the postoperative care of children it must be remembered that manifestations of discomfort are not so insistent as in adults, and that children do not often complain, so that in such matters as the detection of postoperative hemorrhages, thirst and pain, there is a necessity for more skilled and careful watching than is essential in adult life. Irrespective of the kind of anesthetic or the length of its administration, thirst becomes a prominent factor and definite instructions should be left for its relief. The same is true of pain, there are many instances in which its occurrence can be predicted with certainty and it then becomes a duty to anticipate it by the use of some means to minimize its intensity.

But most often the efficient management of postoperative convalescence begins before the operation. There are three large classes of children that come to the surgeon for elective surgery: first, those with a surgical condition which interferes with the general health; second, those with a surgical condition which has little or no effect on the constitutional condition, who might be considered normal if it was not for the surgical condition, and lastly, those who, irrespective of their surgical condition or its influence on their general health, exhibit unmistakable evidences of nutritional faults which, while possibly not much exaggerated by their disease or injury, will become important factors when surgical intervention is contemplated.

In the first class, the relief of the disease or injury is all that is required because the surgical procedure is not interwoven with any problems dealing with constitutional depression independent of it. The restoration of the patients to normal efficiency is a question of surgical relief plus ordinary hygienic care and diet.

There is a similar proposition in regard to the second class also, because the surgical condition is largely or wholly responsible for any constitutional symptoms. We ought not to be satisfied, however, with the mere restoration of a balance which follows the elimination of the surgical cause, but should go beyond this and restore normal rather than relative efficiency.

The third class needs more attention before and after than during the operation. Here then, is the opportunity for the most skilled assistance and counsel obtainable, so that the mortality may be reduced, the morbidity lessened and postoperative convalescence shortened and made more certain and comfortable.

While the general attitude of the public toward surgical procedures in children is not what it should be there are several definite factors which have led to its unconscious formation. Inaccurate diagnoses are more common in children than in adults and incomplete diagnosis is the rule rather than the exception, both being brought about largely by the lack of intimate knowledge of children in general and the manner in which they react to injury or disease.

An inaccurate or incomplete diagnosis often, although not invariably, leads to inadequate treatment and, as a consequence, the child suffers either from too much or from too little surgery. Inadequate preparation of the particular patient and his surroundings is commonly evidenced by the inefficient examination and observation which precedes the operation; there is often inadequate operative care because no special attention is paid to planning for rapid work, a brief and skilfully administered anesthetic, the most efficient assistants and the maintenance of body heat. And it is a far too common fact that an unpleasant postoperative convalescence is commonly the end of an otherwise perfect procedure because the child has not been understood and safeguarded at every point. Postoperative complications are not always directly due to the surgical procedure; a prolonged postoperative convalescence is rarely a surgical proposition and the surgeon is not always capable of handling the whole proposition because at one period there existed a definite surgical problem.

If there is to be a restoration of public confidence which will give the surgeon his due, it must come through a correction of the inattention to those things which surround and bear on the operation itself and a closer relationship between the surgeon, the family practitioner and the pediatrist. Operative procedure is not sufficient; the little one must be returned to its parents not alone surgically relieved but equipped for efficient childhood.

42 Gates Avenue.

ABSTRACT OF DISCUSSION

Dr. Frank C. Neff, Kansas City, Mo.: Sometimes it is the custom for a nose and throat surgeon to operate on a child without the immediate knowledge of the physician who has often observed that child. I have had two instances in which such work was responsible for a grave condition which might have been prevented had the surgeon first obtained an accurate history of the child's previous condition. The first child had been a victim of periodic vomiting, and if I had known the child was to be operated on I think certain suggestions regarding the anesthetic and subsequent care of the patient with regard to washing out the stomach, etc., would have been of some value. It seems that in this case the child vomited for three days following the administration of the anesthetic, which was administered by a capable man.

In the second case, the child had been to some extent a bleeder and had quite a profuse hemorrhage after the removal of the tonsils. It is not probable that the previous history of hemorrhage would have been disregarded had the child's regular physician been consulted.

Dr. Frank W. Pinneo, Newark, N. J.: Children are the most helpless patients and although we have learned to view their feeding and medication from a pediatric standpoint their surgery has not yet reached this state. Chloroform is so dangerous because it is given to a small child in an indeterminate dose for an indefinite period that surgeons are giving up its use. Does the anesthetist think, for instance, of the result of the excitement produced by the anesthetic on the child as one of the causes of sudden death? Does he know that death may follow after a considerable number of minutes and yet be the result of the anesthetic? Does he realize also that the renewal of an anesthetic after a few hours is fraught with danger of sudden death, especially in children? How often do we hear it said by excellent and responsible men who work with children, "This is but a slight operation; we will just give him a whiff of ether." A child is more subject to shock and narcotic than an adult. Because a child is easily anesthetized should we "smother" him with an anesthetic that he will remember all [illegible] with terror of surgery and surgeons? In this [illegible]
conditions that a child may have [illegible]
surgery that he should never [illegible]
Better to postpone operation th[illegible]

terror Long operations are very bad So also is rough handling of tissues necessary through haste Standing between the two we may have to choose Bloodgood emphasizes the importance of short anesthesia but he also recognizes the shock of rough surgery and says that he would rather prolong the anesthetic and handle the tissues carefully and gently, especially in children

Dr Kerr suggests a number of excellent diagnostic points on appendicitis and meningitis Osler says that there is 'no symptom of meningitis present in a child which may not be present when there is no inflammation of the meninges at all" Lumbar puncture, therefore is indicated, if not needed, for diagnosis And how important and sometimes difficult, is the differential diagnosis of appendicitis and functional intestinal toxemias?

Dr H J Gramling, Milwaukee Wis A number of cases have been reported in which death was probably not due to the anesthetic but to the persistence of the thymus gland

MODIFICATION OF THE FERGUSON OPEN-DROP METHOD ETHER-INHALER, AND MODE OF ETHERIZATION

C E PRUDDEN, M.D
DULUTH, MINN

After extended hospital use of the ether-inhaler devised by Robert H Ferguson, M D, of East Orange, N J, for the maintaining of surgical anesthesia by the open drop method, and having become thoroughly impressed with the advantages of its use I employed the principle of construction in a modification which I believe has several advantages over the original

Using the principle of the Ferguson inhaler as a working base I have added to it the simple and well-known celluloid gas chamber and rubber mouthpiece of the ordinary nitrous oxid gas-inhaler

The apparatus is not so complicated as one would suppose on first inspection It consists of a double copper-wire frame The inner frame (A Fig 1) is a convex frame of four wires fastened to the base wire, the outer frame (*B* Fig 1) is of a heavy wire ring supported by four wire legs This is attached to the celluloid face piece (*C* Fig 1) Over the inner frame (A Fig 1) are stretched several thicknesses of surgical gauze which is held in place by a wire loop (*D*, Fig 1) that slips tightly over the gauze

The wire frame with the gauze is then covered with a hood of oiled silk having a draw string at top and bottom The bottom string when drawn tight and tied around the base wire will keep out all air from below the top string is drawn up until only an opening of about an inch in diameter remains Through this opening the ether is dropped (*not poured*) on the inner gauze hood which is made of eight or ten layers of gauze

The rubber mouthpiece (*F*, Fig 2) is then slipped over the celluloid frame and inflated by blowing into the valve and then tightening the valve to hold the air which acts as a seal and face-cushion (Fig 3)

Should it be desired to have the patient in the lateral position instead of the supine a hood with an opening in the side instead of at the top may be used

When assembled for use the inhaler consists of two chambers (A and *B* Fig 2) and when ether is dropped through *C* in the hood *D* it falls on the gauze *E* supported by the wire frame and volatilizes thereby saturating the air in the chamber A

Air saturated with ether is of a higher specific gravity than pure air and is drawn and falls through the gauze into chamber *B*, where it is inhaled as a vapor by the patient

The rubber mouthpiece fits tightly over the mouth and nose and conforms to the contour of the face and allows no air to enter from below into chamber *B* This advantage of fitting tightly to the face does away with the greatest disadvantage from the use of the Ferguson inhaler namely, the use of towels either wet or dry which are commonly used around the base of the Ferguson inhaler to exclude the air from below It will also be found unnecessary to place a towel or covering over the patient s eyes to guard against any ether which might run into them

The placing of a covering over the patient's eyes will often at the onset of anesthesia produce a sense of fear in patients by excluding their vision for they feel that something is about to be done which they should not see, something mysterious, and they at once lose confidence in the anesthetist, which above all should be guarded against, especially in children and hysterical women Omission to cover the patient's eyes also has the advantage of not obstructing the movements of the anesthetist, by relieving him of the necessity of having continually to remove a towel to expose the eyes in watching the pupils for contraction and expansion

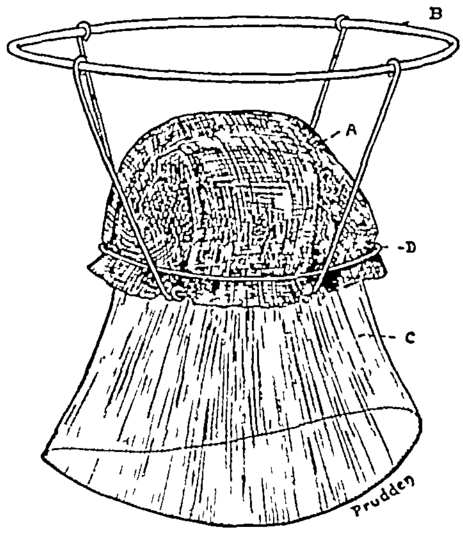

Fig 1 —Frame of inhaler showing wire construction and gauze pad in place

MODE OF ETHERIZATION

The inhaler is held in place over the face by the left hand the third and fourth fingers holding up the jaw, the right hand is free to drop the ether at the rate of three or four drops a second Through the transparent celluloid frame of the lower chamber (*B*, Fig 2) can be noted the condition of the mouth, the color of the lips can be watched and the presence of saliva and mucus can be observed quickly and the inhaler hastily removed to clear the mouth and nose of foreign matter

The patient is first shown the inhaler and is told that placing it on the face will in no way interfere with his respiration, he is also *told that the first few inhalations* will be unpleasant and that at one stage of the anesthesia there will be a slight choking sensation which will pass away with a few deep inspirations he is told to breathe naturally and not to resist the anesthetist, but to allow himself to be overcome by the ether

The anesthetist then has the patient's confidence which is so much desired for a successful anesthesia, the patient understands that the responsibility of getting rid speedily of any unpleasantness rests with him and he will cooperate by breathing deeply, which will in great part do away with the initial persistent fixation of the chest so annoying to the anesthetist

The inhaler is then gently placed over the mouth and nose, a few inhalations are allowed to demonstrate that breathing will in no way be interfered with and then the ether is slowly dropped on the gauze through the opening, gradually at first so as not to frighten the patient, and also to produce an analgesic effect on the mucous membrane of the posterior nares, pharynx and larynx, so that it becomes tolerant to the ether vapor The ether is then increased in rapidity of drops to the second, surgical anesthesia will be produced in from four to nine minutes, generally without any manifestations of the so-called second stage or stage of excitement Should the chest become rigid and the breathing cease for a short period the anesthetist should not be alarmed and remove the inhaler, as this stage will soon pass if the lower jaw is forced forward of the upper and the ether is increased The anesthetist may maintain surgical anesthesia for hours by controlling the number of drops of ether and watching the general condition of the patient, the lips, pupils and pulse, the latter by means of the little finger of the left hand placed on the facial artery where it crosses the inferior maxilla this being done while holding the jaw, or by discontinuing the anesthetic a few seconds and taking the pulse by the index-finger of the right hand on the temporal artery just anterior to the ear

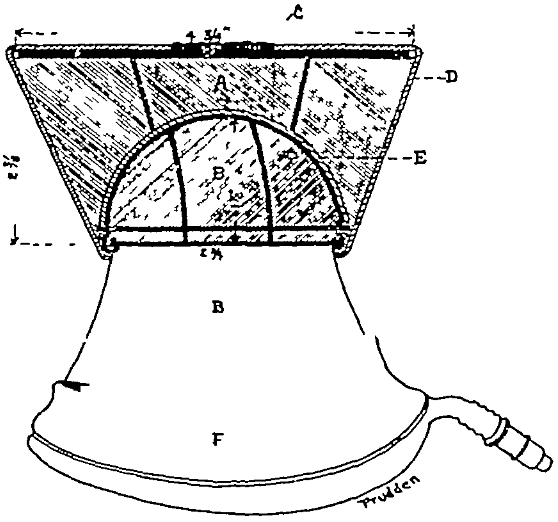

Fig 2—Sectional view of inhaler

Better results will be produced by continually dropping the ether and gauging the amount than by rapidly dropping the ether from time to time with long intermissions

Rarely, if ever will nausea and vomiting follow the use of this inhaler with the anesthetic given as directed, and the recovery is speedy

After the anesthetic the oiled silk hood and gauze pad are removed and the whole frame dipped into some antiseptic solution, dried and a new gauze pad and hood added, when the inhaler is ready for another anesthetic

Whether or not the much-disputed statement is true that ether vapor given by the open drop method chills the patient's lungs I have yet to see a case of postoperative pneumonia or bronchitis follow as the direct result of the anesthetic given by this method and with this inhaler

ADVANTAGES FROM USE OF THE INHALER

I have kept a thorough record of 300 anesthesias consisting of the general run of hospital patients those prepared for operation and emergency accident cases both sexes and all ages mostly adults and including neurasthenics, alcoholics and cases of bronchitis In speaking of prepared patients I refer to those who had had a clearing of the bowel, no food before anesthesia and were given 1/150 grain atropin and one-fourth grain morphin (dosage subject to discretion) hypodermically half an hour preceding the anesthetic The latter procedure tends to produce a quieting effect on the sensorium, reduces pharyngeal secretions accentuates respiration and tends to facilitate the giving of ether in the first stage of anesthesia

I have not had the most remarkable results obtained and reported by some clinicians but the following statistics are conservative and based on actual experience in the surgical clinics and have been very gratifying to me

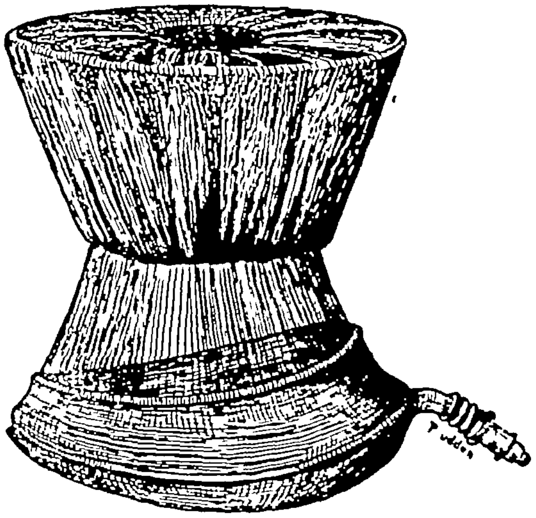

Fig 3—Ether inhaler complete

1 The average time consumed from the time that the anesthetic is begun to the stage of complete surgical anesthesia is six and one third minutes

2 The average amount of ether required to induce surgical anesthesia is 2 ounces

3 The average amount of ether required to keep the patient in surgical anesthesia is 6 4/5 ounces

These figures vary greatly according to the patient it takes from four and one half to nine minutes and from one-half to 2½ ounces of ether to induce surgical anesthesia It will be found that as the length of time of the anesthesia increases, the amount of ether used will decrease and so a short anesthesia of a few minutes may require more ether than the whole second hour of a continued and long anesthesia

The air cells of the lungs become so saturated with the ether vapor during a lengthy anesthesia that it will require very little to maintain an even stage of relaxation and not a too profound narcosis I have repeatedly observed anesthesias with the use of other inhalers in which it required from twenty to thirty minutes to secure sufficient relaxation in the patient to allow the surgeon to proceed the patient would [illegible] cyanotic, breathing would cease the [illegible] have to be discontinued until the prolapsed tongue was brought out of the throat, and artificial respiration would be resorted to and recourse made to the too convenient hypodermic. Generally in these cases the anesthetist has flooded the inhaler with ether and used from 12 to 18 ounces of ether an hour. Of course these cases are rare now, owing to the more intelligent training of anesthetists and to the employment of the open-drop method inhaler.

This inhaler can be made easily with the aid of a pair of pliers and some copper wire and by following the accompanying illustrations. The celluloid lower chamber (*C*, Fig. 1) and the rubber mouthpiece (*F*, Fig. 2) can be procured from any surgical supply house and the oiled silk hoods can be quickly sewed together on a machine.

A summary of its advantages follows:

1. There is absolute freedom from any face covering except the rubber mouthpiece, affording the anesthetist a constant and unobstructed view of the patient's face and condition of the pupils and relieving the patient of fright which would follow the use of a face covering of towels excluding his vision.
2. The inhaler fits snugly to the contour of the face, thus eliminating all air from around mouthpiece.
3. Through the transparent celluloid face-piece, saliva, mucus and the color of the lips can be noticed.
4. Absolute safety is secured owing to the reduced amount of ether required.
5. The administration of ether is simple.
6. The stage of excitement is reduced to a minimum.
7. Surgical anesthesia is produced rapidly.
8. Postoperative vomiting and nausea are infrequent as a direct result of the ether.
9. The same inhaler fits both children and adults, and is adapted to both the dorsal and the lateral positions.
10. Ether may be administered with this inhaler in cases such as alcoholism and bronchitis in which ether is contraindicated when given otherwise than by the open drop method.

NITROUS OXID-OXYGEN ANESTHESIA WITH REPORT OF A FATAL CASE

MOSES SALZER, M.D.
Anesthetist to the Jewish Hospital
CINCINNATI

So much has been written of late concerning the safety of nitrous oxid-oxygen anesthesia that it seems to me a note of warning ought to be sounded as to the dangers and difficulties of administration so that an anesthetic agent as valuable as nitrous oxid should not fall into disrepute. Despite the assertions of the nitrous oxid manufacturers and the exploiters of the machines, nitrous oxid-oxygen is not the safest anesthetic in the generally accepted sense of the word. Outside of dental work or momentary anesthesias it is not nearly so safe in the hands of the inexperienced as is ether. The margin of safety between surgical anesthesia and death is much larger in ether than in a gas-oxygen anesthesia, and I therefore believe that if nitrous oxid were used as extensively by the inexperienced as is ether the [illegible] operative mortality would be higher.

I [illegible] add here to the reported cases another death [illegible] nitrous oxid. The anesthetic was being administered [illegible] during my absence from the city by my intern [illegible] possibly seventy-five or eighty other anesthesias and had had little or no experience with nitrous oxid.

The patient was a woman aged 40 who had had repeated attacks of gall-stone colic associated with jaundice. At the time of the operation apart from a slight icterus she was apparently in excellent health. Examination of the chest and urine showed nothing abnormal. Morphin, one quarter grain, and atropine 1/100 grain had been given hypodermatically one hour before the beginning of the operation. The operation itself was a very simple one and had proceeded to the stage of sewing the opened gall-bladder to the peritoneum, the stones having been removed. At this time, which was between twenty and twenty-five minutes after the anesthetic had been started, death came suddenly with an intense cyanosis. There had been some cyanosis during the operation. The respirations and pulse stopped almost immediately and there was absolutely no return of either, despite the fact that massage of the heart through the diaphragm and *artificial respiration* were kept up for several hours. Cyanosis either continuous or intermittent is always a sign of danger and how much, if any, cyanosis can be permitted in any given case can be determined only by the experienced anesthetist.

A perusal of the literature will show that most of the reported deaths due to this anesthetic occurred either in the hands of the wholly inexperienced or of those just learning the administration of nitrous oxid [illegible] not wish to go on record as being opposed to [illegible] of nitrous oxid-oxygen anesthesia, as I personally [illegible] it the preference in all my anesthetic work [illegible] believe that it ought to be used whenever possible [illegible] not by the occasional anesthetizer. The numb[illegible] factors which come into play in the administratio[illegible] this anesthetic are greater than in any other anesth[illegible] and as the margin between surgical anesthesia [illegible] asphyxia is so narrow as compared with the margin of safety in ether this is essentially the anest[illegible]ic for the expert. But the fact that the anest[illegible]ires [illegible] skill in its administration is no more excuse [illegible] using it than that a life-saving operation shou[illegible]fuse[illegible] a patient because it requires skill in its p[illegible]

Let us consider those factors which [illegible] the difficult administration of this anesthetic [illegible]st place nitrous oxid-oxygen anesthesia is a fixed [illegible], as the vast majority of cases require a preliminary injection of morphin in order that a smooth anesthesia with muscular relaxation may be obtained. When morphin is not given and in a certain percentage of cases when it is administered ether is necessary for muscular relaxation and still further complicates the anesthesia. Morphin outside of its narcotic effect which is of value, exerts an even more important influence on the respiratory center in that it increases the tolerance to carbon dioxid and thus allows of the administration of a mixture richer in gas than would otherwise be the case. A slight increase in the arterial carbon dioxid content is a much more potent cause of hyperpnea and a resulting overanesthetization than is a comparatively large diminution of oxygen. Haldane and Priestly[1] have shown that an increase of 0.2 per cent. of carbon dioxid will double the respiratory rate. When nitrous oxid-oxygen is administered without the preliminary morphin injection, the hyperpnea is of serious import and prevents a smooth anesthesia. Nitrous oxid itself is also a respiratory depressant, and this added to the morphin action makes the danger of asphyxiation always a real one. On the other hand, without the use of morphin, the respiratory rate is increased, more nitrous oxid is inhaled and absorbed and there is again the danger of asphyxiation, plus an irregular anesthesia to contend with In either event, the nicest judgment and skill are necessary to conduct a safe and satisfactory anesthesia Nitrous oxid cannot be administered by any automatic machine, neither can any other anesthetic, as neither patient nor operators are automatic

---

[1] Haldane and Priestly: Jour. Physiol., 1892, xiii, 419.

Nitrous oxid-oxygen given with ether again complicates the physiologic workings of the anesthetic Nitrous oxid with "just a little ether," or with more than "just a little" *given continuously throughout an operation* should not be considered as a nitrous oxid anesthesia at all, but as an ether anesthesia modified by nitrous oxid

Nitrous oxid-oxygen-ether anesthesia does not present nearly the difficulties in administration as does nitrous oxid-oxygen without the ether Ether is a respiratory stimulant and counteracts the depressing action of both nitrous oxid and morphin It is much more powerful as an anesthetic agent, volume for volume, than is nitrous oxid Therefore those who give "just a little ether," say 1 or 2 per cent, throughout an entire operation (which in some cases may mean 2 or 3 ounces), are able to use possibly 5 or 10 per cent less gas, for which oxygen can be substituted, which is from five to ten times the leeway allowable when ether is not used and when a difference of 1 per cent in the gas or oxygen spells success or

ntain that when ether in any amount is given ously during an operation the anesthesia is essen- n ether anesthesia and the patient is subjected to ingers and disagreeable after-effects of ether ng from the amount of ether some administer with is-oxygen, these gases simply serve to vaporize the , an expensive and unnecessary procedure, as the ul anesthetist can conduct an ether anesthesia even for prolonged operations with from 2 to 4 ounces of *ether without the gas When the ether is given only for* a few minutes early in the anesthesia this is also essentially an ether anesthesia until all ether effects have been eliminated

I do not wish to appear as condemning this combination, as there are cases in which anesthetization is unsatisfactory or impossible without ether, and if anesthesia by the use of an ounce of ether plus the gas and oxygen is satisfactorily maintained I believe that the patient is better off than if he has taken 3 or 4 ounces of ether without the gas and oxygen, but these should not be called nitrous oxid anesthesias To summarize

1 Nitrous oxid-oxygen is not the safest anesthetic for the occasional anesthetist, and should be administered only by the expert

2 The number of physiologic factors involved are greater than with any other anesthetic

3 A preliminary injection of morphin should always be given

4 Ether modifies the anesthetic and makes it easier to administer, but subjects the patient to the dangers and disagreeable after-effects of ether

41 Croton Building

Recent Work in Anesthetics—Although the foundation of most of our knowledge of the action of anesthetics has been laid bare through experiments with chloroform clinically and in the laboratory it now appears that both physiologists and anesthetists are beginning to regard this drug as having yielded to us all it can and are turning their attention elsewhere In America as we have seen ether holds the field to a very large extent although at the moment that field is being encroached on by administration of nitrous oxid and oxygen—J Blumfeld in *Practitioner*, London

RESUSCITATION FROM DROWNING

CONTINUED PERSISTENCE OF HEART-BEAT DEATH FROM NON-RESUSCITATION OF THE RESPIRATORY CENTERS

FREDERIC WADE HITCHINGS, S B M D
CLEVELAND

The frequent occurrence of drowning-accidents during the summer serves to emphasize the need of a thorough understanding of the principles underlying resuscitation and particularly the fact that success ultimately depends on preventing permanent injury from anemia of the brain There is need of extensive series of figures based on accurate observation of similar accidents which will show the important part the time element bears in such cases In the following case, while resuscitation was not accomplished, the facts seem to be worth recording because the heart continued to beat for so long a time while artificial respiration was being given

The patient was a strong, well developed man aged 28, who had apparently been seized with cramps while swimming in about 7 feet of water When attempts were made to get him out of the water he struggled so hard that he not only prolonged the efforts but also nearly drowned two of his rescuers In all probability he was submerged between four and five minutes After he was brought ashore the water was pressed out of his lungs at once his tongue was drawn forward and artificial respiration was begun by the Sylvester method

On my arrival, about fifteen minutes after the accident, I found the patient with markedly cyanotic face and no radial pulse I at once gave him a couple of sharp slaps over the heart and turned him over on his face so as to continue the artificial respiration by the Schäfer method Within the next few minutes feeble heart sounds could be heard with the stethoscope and a little later a faint pulsation at the wrist could be obtained. In the meantime Dr J B Austin had been sent for at my request, and from this time on we worked on the patient together, Dr Austin confirming the subsequent findings

At the end of about half an hour after the beginning of artificial respiration the face began to be a little less cyanotic and three slight spontaneous respirations were obtained Oxygen was then given continuously It seemed as if success would ensue but in spite of strychnin, one thirtieth grain and epinephrin 10 minims of a 1 1,000 solution being given intravenously and massaged thoroughly toward the heart it was impossible to bring back spontaneous respiration The heart continued to beat until two hours and ten minutes had elapsed the artificial respiration being given for a total time of two hours and fifteen minutes and the oxygen for the last one and three quarters hours of that time

This case illustrates the well known fact that efforts at resuscitation should be used for at least two hours after apparent death although I do not believe it is of any use to do this for so long a time in case of persistent absence of the heart sounds as shown by careful stethoscopic examination In this regard in another drowning case which I was called to attend a few days previously a 14 year old boy had had cramps and been submerged between five and ten minutes—probably nearer ten minutes than five No heart action could be detected and as I saw him after there had been no evidence of heart action for about twenty five minutes the case at once seemed to be hopeless Resuscitatory measures had been maintained for three quarters of an hour when a drop of ether was placed in one eye (d'Halluin) No reddening was caused confirming the previous findings that there was no circulation If artificial respiration had been continued for an hour longer [illegible] unnecessary effort in the face of [illegible]

The heart may continue to beat for as long a time as five minutes after cessation of respiration, although it usually stops in two or three minutes Add to a *possible* five minutes the seven minutes during which the brain may be completely resuscitated after total cessation of the heart-beat, a *possible* maximum of twelve minutes of relative death may be undergone with recovery If this period of twelve minutes is exceeded "recovery" may take place but without return of consciousness or with destruction of some of the higher centers Moreover if the heart does not pump a sufficient stream during the first five minutes the time is shortened Another dangerous factor tending to shorten this time is the degree of violence with which the water enters the lungs when the accident happens

In case preparations can be made inside of this twelve-minute limit the attempt should be made to inject epinephrin in normal saline solution into a radial artery toward the heart (Crile) In this way the coronary blood-pressure can be raised and the heart made to resume its action Doing this on the field would mean taking chances as regards infection but with a life at stake it would be legitimate to make the effort The hands of the operator and the wrist of the patient could be sterilized with tincture of iodin No anesthetic would be needed nor could it be used if at hand The needle, tube, reservoir and saline solution would have to be in a portable form ready for instant use

In the case reported above, failure to resuscitate was due principally to irreparable damage having been done to the respiratory centers in the medulla by anemia In this case there was no indication for using the saline epinephrin intra-arterial infusion because the heart was resuscitated without doing so The intravenous injection of epinephrin and strychnin must have been dispersed through the circulatory apparatus but epinephrin and strychnin will not cure cerebral anemia — they merely enable the circulatory mechanism to work more efficiently

With the exception of the Brosch-Sylvester method, the Schafer method of giving artificial respiration gives the greatest respiratory exchange per movement of the thorax When in addition to this the facts are considered that the tongue automatically falls forward that there is free drainage from the lungs and that long continued application can easily be made it is undoubtedly the best method to be used in drowning-accidents

10406 Euclid Avenue

The "Drug Action" of Anesthetics—Richard Gill chief chloroformist to St Bartholomew's Hospital maintains that the "drug action" of all anesthetics is similar they are all oxidized in the blood into inert bodies they deprive the red cells of their oxygen The hot nascent oxygen of the red cell readily oxidizes them whereas the diluted oxygen of the air does so only with extreme slowness The red cells at first offer a resistance to this demand for their oxygen The resistance progressively diminishes Less and still less anesthetic is [illegible] during a long operation as the minutes pass and much more anesthetic is needed to break down the first resistance (induction) than is subsequently needed to deoxygenate the red cells already beaten by the anesthetic (maintenance) The oxygen instead of feeding the body tissues is confiscated [illegible] the anesthetic state" is one of oxygen starvation An oxygen-starved brain and nervous system [illegible] cannot function fully hence [illegible] insensibility —J W Dean in *Australasian Med Gaz*

THE ABILITY OF MOTHERS TO NURSE THEIR CHILDREN*

J P CROZER GRIFFITH, MD
Professor of Pediatrics in the University of Pennsylvania
PHILADELPHIA

Perhaps this topic may well be opened by emphasizing the necessity for women to nurse their children particularly as so much misconception exists regarding this not only on the part of the laity but of physicians themselves I have heard expert physicians say that they have little fear of difficulty in feeding an infant artificially if only they can have the charge of it from the beginning I thoroughly agree with the necessity of the early control by the pediatrist in order to avoid the digestive disturbances which so readily arise The difficulty is thereby lessened, but by no means removed I cannot share the optimistic view expressed There may exist the man who can, under these circumstances feed infants as successfully artificially as at the breast but I have yet to meet him Certainly, all statistics indicate the contrary A few of these may be of interest

INFANT MORTALITY AND INFANT DIET

The oft-quoted extensive studies of Eross,[1] based on the vital statistics of thirteen European countries covering a number of years show that the average mortality in the first year of all children born alive is 18 33 per cent The United States Census Reports[2] for 1890 give a very similar figure — 18 29 per cent for the registration area There is considerable variation in different parts of the world According to Eross, the mortality in Ireland is but 9 4 per cent and in Sweden 9 7 per cent in Saxony, on the other hand 28 1 per cent, and in Bavaria 28 7 In Russia according to Gundobin,[3] it is still higher, 32 6 per cent Budin[4] reports a mortality in the first year for France from 1896 to 1900 of 20 2 per cent and the statistics of Luling,[5] for Baudelocque's clinic de Paris give 26 94 per cent dying in the first year of the 13,952 children born

That this mortality is largely dependent on disorders of digestion is a suggestive fact Heimann[6] reports an average from 1897 to 1901 inclusive of 10,993 infants under one year of age dying each year in Berlin over one third of them suffering from digestive disorders In the mortality of Massachusetts from 1892 to 1896 according to S W Abbott[7] diarrheal disorders were responsible for 29 19 per cent of the deaths in the first year of life The six-year record for the United States ending 1890 made diarrhea responsible for 21 22 per cent of the deaths in this period Budin[4] found that 38 5 per cent of the deaths in the first year in the civic population of France were due to gastro-enteritis

This brings us naturally to the next point to be considered the influence of the diet since it is particularly among the artificially fed infants that gastro enteric affections prevail We have reason to expect then, that the mortality will be found much greater in the artificially fed That this is the case is well recognized but a few figures may serve to illustrate to what degree it is true In the cases reported by Luling,[5] 14 24 per cent of the breast-fed infants died and from 31 42 per cent to 50 24 per cent of the bottle-fed, and in the 10 000 infants in the first year studied by Westgaard,[8] of those that were breast-fed 17 per cent died from gastro-intestinal diseases and of the bottle-fed 43 per cent Of 1,000 infants studied by Armstrong,[9] in England, but 8,418 per cent of the breast-fed died in the first year against 22 826 per cent of the bottle-fed In 8,329 deaths under one year of age, occurring in Munich, Frank[10] found that 86 14 per cent of the infants had been bottle-fed Finally, W H Davis[11] *addressed letters of inquiry* to a large number of women giving birth to children in 1910 in Boston The 736 replies showed that only 26 per cent of the deaths between two weeks and one year of age had occurred in breast-fed babies Roughly speaking, we may say that the breast-fed baby has at least five times the chance of living that the bottle-fed baby possesses

We may then assume it proved, beyond question, that the absence of breast-feeding is perhaps the chief cause of infantile mortality in the first year, as indeed of many deaths occurring in the second year We may even go further than this and claim that the results of bottle-feeding are often much more lasting than this period Thus Rose[12] studied 164,000 persons with relation to the later influence of the diet which had been given in the first year of life, and found that in many respects the deleterious effects of bottle-feeding were often quite discoverable in these individuals, and that even in men capable of military service the difference to the disadvantage of the bottle-fed baby was very apparent This observation is by no means an isolated one, similar conditions having been noted by other writers

BREAST-FEEDING AND THE CONDITIONS AFFECTING IT

With the full understanding of these facts, the importance of the next three topics to which reference must be made is pressed home on us 1 How many mothers nurse their children? 2 How many are capable of nursing? 3 What is the cause of failure of women to nurse their infants?

The condition varies considerably with the country In Japan breast-feeding is the rule In Greenland, artificial feeding is scarcely known and among the Esquimaux of Alaska, there is no cow s milk to be had and infants are often nursed for from two to three years In some of the races of Africa, the mother is often helped, if need be by any of the women of the village, previous parturition recent or at all, not being a necessity the secretion of milk being gradually established in virgins or in grandmothers by the repeated putting of the child to the breast

The importance of nursing by the mother is one long recognized by writers An interesting contribution by Schlossman[13] quotes the urgent advice given in favor of it by the philosopher Favorinus who lived in the time of Trajan Unfortunately however in many so called civilized countries maternal nursing has undoubtedly decreased greatly in frequency since then In parts of Bavaria according to Grassl[14] hardly 30 per cent of the mothers give the children the breast In Berlin as stated by Neumann,[15] 55 2 per cent of the infants were nursed in 1885 and only 31 4 per cent in 1890, showing the great falling off which had occurred in maternal nursing Further statistics could be given

Is this failure of breast-feeding an actual inability or only an apparent one? Is there in reality a diminishing power of women to nurse their infants? This is our second question As a result of studies in the Obstetrical Clinic of Graz, Negris[16] found that there existed in only 10 per cent a physical disability to nurse In the Stuttgart clinic, according to Martin[17] nearly 100 per cent do nurse In Heidelberg Jaschke[18] observed that whereas in 1904, 64 01 per cent of the infants were breast-fed, in 1907, 86 14 per cent and in some months 97 22 per cent were showing a very decided increase in the ability In Wurttemberg, where formerly according to Hegar only 41 per cent of the women in the clinics nursed their babies now according to Martin[17] 100 per cent were capable Madam Dluski[20] estimated that of 500 women observed in Pinard's clinic in Paris there were but five in whom it was certain that nursing would have been impossible either from the beginning of lactation, or after an interval of continuous effort and Blacker[21] as a result of studies on 1,000 children in London, could find only twenty-four, or 2 5 per cent, in whom there was a physical inability to nurse

With regard to the frequency of breast-feeding whether there is an actual diminution or an apparent one only, some of the figures which have been given, are, to a certain degree, open to criticism In the first place many of the statistics are derived from lying-in institutions for patients of the poorer classes only among whom the conditions of life are very different from those which obtain among the well-to do In the second place, such statistics apply only to the first few weeks of *the nursing period during which* the women are under close observation and careful diet and treatment, and we have no means of knowing how many of these women are able to continue nursing say, for *six months* or more, or do so even if able after they return to their homes The important matter to determine is whether there is a diminution in the actual ability of women to continue nursing, or whether the cessation of nursing is a preventable condition Exact figures bearing on this are not very numerous In Leipsic according to Hohlfeld[22] only 27 5 per cent of the mothers continued to nurse for six months Weiss[23] found that in 1 622 cases studied by him there were 77 01 per cent of the infants nursed for one week and only 25 3 per cent fed in this way for over six months Negris[16] found that among the polyclinic clientele of Graz and its vicinity only about one-third of the mothers continued to nurse exclusively for a period averaging two months or more and that this number was diminishing Nordheim[24] reported his experience in 1 000 women coming to the Children s Dispensary in Munich Of these only 3 6 per cent had nursed longer than three months and only 0 8 per cent longer than six months This is truly as Nordheim says a deplorable condition

More encouraging are the interesting figures of Deneke and Thorn[25] who through the aid of midwives-who had been in attendance studied the later history of 2,447 infants born in the Magdeburg district in 1907, outside of maternity institutions. It was found that 8[illegible] 7 per cent. of these were nursed at least for a time, and that in 61 per cent. nursing was continued for longer than two or three months. They conclude from these studies that the great majority of mothers are physically capable of nursing their children. Hegar[26] is of the opinion that under careful management 60 per cent. of mothers outside of maternities are able to nurse their infants. Kriege and Seutermann[27] in 4,096 infants in private practice in Barmen found 77.9 per cent. nursed for from five to six months. Koplik,[28] in 1,007 cases in private practice in New York found less favorable conditions. Only 573 (56 per cent.) of these were breast-fed for different periods and only 40 per cent. of these 573 for longer than four months. Marfan[29] on the other hand, estimated, as evidenced in his own practice, that two-thirds of the women of Paris can nurse satisfactorily and in the other third there is generally a partial power to do so, a certain amount of substitute feeding being required; only 10 per cent. are actually unable.

The question then of the falling off of maternal feeding can be determined only partially on account of the variation in published statistics. Undoubtedly many more women cannot nurse than should be the case among supposedly normal individuals. Undoubtedly, on the other hand, many women do not nurse who are capable of doing so under proper care.

The relative inability among the poor and the well-to-do is also a matter of interest. The general opinion appears to be that in the better classes the inability to nurse, or at least the infrequency of nursing, is seen more markedly than among the poorer classes. There exists certainly among the upper classes a large number of women who do not and often, in spite of their most earnest wishes, cannot nurse their infants. Contrary to the common opinion is, however, that of Neumann,[30] who thinks that the falling off in the capability of maternal nursing in Berlin women is seen oftener in the working classes. From the years 1900 to 1905 there occurred in that city an increase in breast feeding among the well to do. The small percentage of Vienna infants nursed over six months as reported by Weiss[2[illegible]] came too from the dispensary class of patients.

Some of the statistics of maternities quoted are at least a clear indication of the general change which it is to be hoped is taking place. The clearly increasing number of women in some of these institutions who now nurse their children as compared with the conditions a few years earlier indicates that a similar increase of frequency of nursing is to be looked for in patients outside of the institutions. Certainly everywhere among the more intelligent classes and even among the poorer under the influence of the awakened conscience of physicians and the instruction which mothers receive from varied sources there is a growing earnest desire of women to nurse their children and, it would seem, an increasing frequency of maternal nursing.

This brings us to our last question: What is the cause of the diminution of breast feeding which has shown itself in many regions? Bunge[31] believes that there is an increasing actual physical inability of the mother to carry on maternal feeding, which he attributes largely to the continued use of alcohol by civilized races. Whatever the cause, there is good reason to believe that there is a physical disability to a certain extent and that this disability may be transmitted by inheritance. Most investigators, however, think that the causes of failure to nurse are to be sought rather in the unwillingness of the mother, instigated or abetted often by the advice of midwives and monthly nurses and, I regret to say, far too frequently by physicians to make a fair effort. Hegar[26] expresses this clearly in attributing the inability to nurse to the influence of generations of undervaluing of maternal feeding. The introduction of the numerous methods of artificial feeding led easily to the conviction that nursing at the breast was an unnecessary and onerous affair. Ziegenspeck[32] points out that in Germany, where the preparation of artificial foods and food mixtures has long thriven, dating, as we know, at least from the time of Metlinger (1474 A. D.), maternal nursing has suffered proportionately.

I have, in a previous article,[33] referred to an interesting contribution by Keller[34] which is so illustrative of the curious reasons assigned that I give it now more in detail. Although the observations were made on women of the poorer classes the reasons in many respects are very similar to those commonly given by women in better circumstances. Keller studied the histories of 1,300 children in the Kaiser Franz-Joseph's Ambulatorium in Vienna and found that 278 or 21.4 per cent., had never been nursed at all. In eighty-two of the 278 cases the failure to nurse was on the mothers' own initiative, not through the suggestion of others. The reasons given were: "felt weak," fifteen cases; "felt ill," nineteen; "too young," one; "too little milk," but without any attempt, fifteen; "child would not take the breast," but without trial, six; "no milk," but without attempt, seven; "took bottle readily," six; "menses occurred," one; "had a severe labor," three; "pain in the breast," but child never put to the nipple, seven; "husband unwilling," two. In nineteen cases it was through the advice of the attending physician that the mother did not attempt nursing, and on the following grounds: "sick" or "weak," ten; "menses had occurred with previous child," one; "too little milk," but without trial, two; "no milk," but without trial, six. In seventy-nine cases the advice of the midwife was followed, the reasons urged being: "sick" or "weak," twenty; "too old," one; "no breast," three; "would not take the breast," but no trial made, five; "too little milk," but no trial made, twenty-nine; "no milk," but no trial made, twenty; "tender breast," one. In ninety-four of the remaining ninety-eight cases the reason for not nursing was the necessity of going immediately to work. In only 0.8 per cent. of the cases was it perfectly certain that the mother could not have nursed. Very similar results have been previously published by others, among them Nordheim[24] who found that of 1,000 women 61.2 had never nursed at all, and 86.7 per cent. of these entirely without good reason.

Among the working classes, undoubtedly, poverty is a frequent cause of the desire to avoid nursing. It is often imperative for the mother to work, and she cannot well do this and attend to the infant also. In other cases lack of suitable nourishment for the mother causes a failure in the secretion of milk. The remedies for the c difficulties are to be found only in sociologic aid. In other cases it is the complete ignorance of the mother regarding the importance of breast feeding which leads to gross indifference in the matter, and this applies to all classes of society. Only constant instruction of the people can remedy this. The splendid work of the Consultations de Nourissons, founded in Paris by Budin, and established in other cities of France, has by this instruction increased the number of cases of maternal feeding among the poor by 20 or 30 per cent. Similar efforts in Meran and Stuttgart to care for the better nutrition of the mothers have, according to Ziegenspect,[32] increased their ability to nurse their children. In the upper classes there is undoubtedly often seen an inability to nurse dependent on the more highly organized and hence more easily disturbed nervous organization of the mother. Here, too, is the influence of early mental forcing, early enjoyment of social life, with late hours, and the like. With all classes the failure of intelligent management of the early nursing periods by physicians or midwives has often been sufficient reason for an early cessation of the milk secretion. Faulty methods of dressing have doubtless in the past been the cause of many hopelessly depressed nipples.

The numerous stated contra-indications to nursing are more fancied than real. Actual contra-indications are few, and physicians should learn to appreciate this fact. Here, especially, the obstetrician who is thoroughly grounded in the importance of breast feeding can be of the greatest aid, since he is so early associated with the mother and can exert a great influence on her. Certainly many obstetricians in the past have paid all needed attention to the mother, but far too little to the infant. This is a reproach often made, but one which I hope is passing away. There is there can be no good substitute for mother's milk and this the obstetrician should impress on the mother with all his power.

Finally, in this connection, it must never be forgotten that inability to nurse or inability on the part of the infant to digest its mother's milk can never be determined by a brief trial. It is only after prolonged and repeated, and again repeated, efforts that we can reasonably conclude that weaning is necessary. Here the fault lies with physicians, since they are, as a rule, far too ready to abandon their efforts. The mother is perhaps clamorous for weaning and it is easy to move in the path of least resistance. Many a time the breast, which at first gives insufficient milk, will later render an abundant supply, and the infant's digestion at first much disturbed, will accustom itself perfectly after a while.

In conclusion, I think it may be claimed (1) that the mother's ability to nurse her infant, although lessened in the past, is no longer materially diminishing provided the woman has been raised and continues under healthy, normal conditions, (2) that these conditions are improving in the upper classes and not changing for the worse in the poorer and (3) that the infrequency of nursing depends chiefly on the ignorance of the laity and the indifference of physicians. It is our duty as physicians to remedy these evils.

1810 Spruce Street.

Metal Poisons.—While it is true that most of the workers in the poisonous metals are warned of their danger, my experience with them is that each man usually thinks he will prove an exception to the rule and like the coal miner long accustomed to deal with fire-damp finally forgets the danger and courts disaster.—Thompson in *Jour. Maine Med. Assn.*

SUPPLEMENTAL BREAST-FEEDING IN INFANTS *

H. M. McCLANAHAN, M.D.
OMAHA

Vital statistics have abundantly demonstrated the following facts:

1. Mortality is greater during the first year than at any other time of life, and higher during the first three months of life than during any other period.

2. Mortality and morbidity are higher among bottle-fed than among breast-fed infants. This is the testimony of writers on diseases in children. As there is no evidence that breast-fed infants receive better care than those reared on the bottle, it is evident that the only reason for the greater mortality in bottle-fed infants is due to the nature of the food. The reasons for the difference in mortality may be briefly summarized as follows:

A. The milk of the mother is adapted by nature to the peculiar needs of the human infant just as the milk of other mammals is peculiarly adapted to their offspring.

B. It contains all of the elements necessary to the growth of the various organs and tissues of the infant's body. In the order of nature, the milk of other mammals is not adapted to the digestion of the human infant.

C. Breast-milk is received by the infant in its natural state unchanged by cooling or agitation or the separating of its constituent elements.

D. It is a vital fluid, as it enters the stomach, stimulates the digestive secretions and is assimilated with less waste and induces less exhaustion of the vitality of the infant than any prepared food. Hence there is less expenditure of vital energy in the digestion of mother's milk.

E. Under normal conditions it is a sterile fluid and is carried to the infant's stomach in a sterile condition.

F. It is ingested at an even temperature, namely that of the body, and is at once ready for the action of the digestive ferments.

G. It contains certain protective principles that confer an immunity to the infant, and greatly lessens infant morbidity.

REASONS FOR INCREASE IN BOTTLE FEEDING

While the above facts are common knowledge among students of medicine, they are not duly appreciated either by physicians or by the laity. There is an increasing number of infants being reared on the bottle. It is believed and no doubt correctly that the chief reasons for this increase in bottle fed infants are:

The influence of manufacturers of infants' foods. We must admire the systematic method employed in exploiting the merits of the various foods and we cannot believe that extensive and expensive advertising would be continued even to the mailing to expectant mothers of handsomely illustrated booklets containing specific directions for preparing the food if it were not a paying business.

Improved methods of infant feeding. During the past twenty years there has been an immense volume of current literature on feeding not only in medical journals but also in popular publications and both the medical profession and public have come to believe breast feeding neither essential nor important to the welfare of the infant. On the contrary breast feeding has received scant attention, indeed no other physiologic function of the human body has received so little study as breast-feeding Granting that immense progress has been made in artificial feeding it yet remains true that the best artificial feeding will not equal breast-feeding

---

* Read in the Section on Diseases of Children of the American Medical Association at the Sixty-Third Annual Session, held at Atlantic City, June, 1912.

My limited study of this subject leads me to the conclusion that among both the medical profession and the laity, the belief exists that a mother either can or cannot nurse her infant As Southworth has said, "Milk either comes into the breasts abundantly and is good, or it comes in scantily and is useless" It is the practice, if the mother does not have sufficient milk adequately to nourish her baby, *forthwith to place it on* the bottle Now the question I wish to present for consideration is this Is there no middle ground between entire breast-feeding and bottle-feeding? If the mother has a partial supply of milk why should this be discarded? Is not some breast-milk better for the infant than no breast-milk? The arguments I have presented for breast-feeding apply almost equally to partial maternal nursing Supplemental feeding is not only simple justice to the helpless infant, it is, I believe, beneficial to the mother It relieves her from the drain, if the milk is scanty, it affords her wider personal freedom and while it may sound sentimental, I believe it nevertheless true that breast-feeding stimulates the maternal instinct, and enhances affection for the offspring

Granting that the infant can be reared on the bottle and survive its first year is that all? What about the morbidity of bottle-fed infants? Is it not the general experience that many bottle-fed infants suffer from various forms of indigestion anemia and other diseases of nutrition as scurvy rickets, malformations and general infections, that increase mortality in subsequent years?

I have no statistics to offer, but this is my personal experience I have been giving this subject study for more than five years and during that period have made it a rule in my office work to ask the question whether or not the patient was breast-fed or bottle-fed If the reply was that the infant was bottle-fed, I have endeavored to ascertain the reason As the result of these inquiries I have gathered from 100 mothers who have reared their infants on the bottle, the following information

Only fifteen mothers out of the 400 replied that they positively refused to nurse their infants Three hundred and eighty-five replied that they would have nursed their infants had there not been some reason to the contrary Twenty of this number stated that they were seriously sick following confinement and for that reason could not nurse their infants A number were compelled to wean their infants because of retracted nipples or fissured nipples or mammary abscess and a total of 105 made a failure of breast-feeding during the first two weeks after confinement In about 250 cases the mother said that she had weaned her baby because it was starving or crying or her milk was not nourishing or that she did not have enough milk to supply the infant In reply to the question Did your physician advise mixed feeding? not more than ten gave an affirmative answer I was impressed with the fact that the majority replied that they had never heard of such a thing as mixed feeding To the question "Did your physician examine the breast-milk before advising you to wean the infant the answer was negative in all but [illegible] cases

It is my conclusion that supplemental feeding is not appreciated either by the profession or by the laity This suggests the question "Does supplemental feeding offer any advantage or is it better or safer for the infant than entire bottle-feeding?" As I have already indicated, there is but one answer to this question, but as the experience of any one individual is too limited to have any great value the question can only be answered by the combined experience of many observers

I am firmly convinced that mixed feeding is almost as beneficial to the infant as entire breast-feeding, and I desire earnestly to protest against the fallacious doctrine of *weaning the infant entirely because of insufficient supply of milk or of poor quality of milk or any other reason except some organic disease in the mother* I would urge with all possible emphasis the adoption of mixed feeding in all cases in which there is a deficient amount of milk, and in cases in which the supply of milk is abundant but the mother's health seems to suffer in consequence In these cases I am sure it will be found that supplemental feeding will be of benefit to the mother In cases in which the supply is sufficient but the quality deficient, as ascertained by simple examination of the milk, it is a simple matter to supplement the breast-milk with a modified milk that will make up the deficiency in quality It is a mistake to think that any preparation of milk will do in mixed feeding I am sure failure results from want of attention to this phase of the subject

RESULTS OF SUPPLEMENTAL FEEDING

I wish to report fifty-six cases of supplemental feeding under my care during the last five years In this series of cases I have had the privilege of directing the mother at intervals during her nursing period I freely confess to a number of failures during the same period, but I believe most of them were due to my inability to secure the confidence of the mother In my judgment to attain success, it is essential to have the cooperation of the mother The best way to secure her cooperation is to convince her of the value of the method—that it will not only save her strength but increase the life prospect of her infant, improve its nutrition and confer a relative immunity to disease It is important also that the mother should receive proper medical advice as to her general health

In my experience there are two important difficulties to be encountered and overcome in mixed feeding

1 The infant tends to wean itself from the breast This is the first real serious problem to be met, and without firmness and obedience on the part of the mother failure will result *In some cases it will be necessary to let the baby go hungry for hours* In one case the baby had nothing but water for twenty consecutive hours It then took the breast and never after was there any serious trouble in this case Each time the mother weakens and gives the bottle but increases the difficulty In fact, most failures occur as a result of this tendency

2 Lessening of the quantity of milk If the breasts are not nursed regularly they tend to cease secretion *and also in my experience the milk is of a poorer quality* The use of the breast-pump is a poor substitute in stimulating the secretion

I have found that the safer plan is to give but one entire bottle a day This bottle is usually given at 6 or 10 p m This rule permits the mother to have an evening out, without feeling that she is in any way neglecting her infant At other times the baby is to leave the breast, the time varying owing to the condition of the gland. As soon as the mother feels that it has become soft, the infant is taken away and given the bottle. It is a mistake to permit the infant to strip the breast. This practice is wearing on the mother and likely to induce indigestion in the infant. I have found from experience that ten minutes is usually ample time to keep the baby at the breast. My rule is to let the baby nurse the bottle until it is satisfied. Of course, the quantity will vary owing to the amount it gets from the breast. No rule can be given, but I always have an ample quantity of modified milk prepared. It is my observation that the food should not be too sweet. I have repeatedly observed that when the infant is given condensed milk, there is greater danger of its weaning itself from the breast.

The small amount of prepared food required to cause a gain in weight is surprising in some cases. One of my patients, an infant aged 4 months, had not gained for three months. I was called to advise concerning weaning the baby. In that case the addition of one bottle each evening of 5 ounces caused a gain during the first week. I have frequently observed that supplemental feeding improves the health and general comfort of the mother. In some of my cases the mother would frequently go for several days without giving any bottle. Another advantage is that if the mother feels that she is not quite up to the standard, or that the infant is not gaining normally, bottle feeding can usually be increased.

These fifty-six mothers were from all walks of life. Several were wives of laboring men who were compelled to discharge arduous household duties including washing and ironing. In all these cases the mothers appreciated greatly the relief given by mixed feeding. Three of them were women who were compelled to work all day and to be away from the infant. Two of them found it necessary to pump the breast two or three times a day in order to keep up the supply. Not one of the fifty-six infants were seriously sick during the nursing period. Three developed pertussis, but recovered. All made a satisfactory gain in weight. The mothers were satisfied with the method of feeding, and a number ceased nursing their infants with regret. As a result of my experience and observation, I submit the following conclusions:

CONCLUSIONS

1. Unless the mother is suffering from some serious disease she should nurse her infant.
2. Many failures in breast-feeding occur during the first two weeks, often from preventable causes.
3. It is an unjust aspersion to assert that the mothers refuse to nurse their infants. The majority of mothers will nurse their infants if they realize that it is important.
4. The responsibility for bottle-feeding rests largely on the medical profession. If all physicians believed in breast-feeding and would use their influence with the mothers there would be few infants reared entirely on the bottle.
5. Supplemental feeding provides the infant with the vital elements of breast-milk and to that extent lessens mortality and does not injure the mother's health.
6. Supplemental feeding requires an intimate knowledge of the various modifications of cow's milk and necessitates complete cooperation between mother and physician.

1312 North Fortieth Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. GRIFFITH AND McCLANAHAN

Dr. David E. English, Summit, N. J.: I have used a plan, which has proved very satisfactory. When the mother's milk is scanty and there is not enough to satisfy the baby I have her nurse the baby and feed it at the same time, that is, put it from one nipple right on to the other. I have two reasons for this, one is that I think the baby's stomach should be filled up when fed, so that it does not have to be fed so frequently. The other is that it gets the mother's milk mixed with the modified milk and gets the action of the ferments in the mother's milk—what Dr. McClanahan calls the vital principle. There are three ways in which this may be done: one is to feed the baby modified milk before he is put to the breast; in doing this we have to find out by experiment how much modified milk to give him. Another is to give the breast first. Some babies refuse modified milk after the appetite has been half satisfied with mother's milk. A third way is to give a little modified milk first and then breast milk and then, if the baby will take any more, finish up on modified milk. By using these little tricks, I have not only been able to keep the mother's milk going and the baby well nourished, but also to help it to digest the modified milk better than it would otherwise.

Dr. Henry J. Gramling, Milwaukee, Wis.: When I find a mother who cannot nurse her baby the first thing I do is to put the baby on modified milk at night. If the mother's milk is scanty and she has to get up at night she will not have enough nourishment for the child the next day. If the mother is nervous it is wise to take the baby away from her altogether at night so that her sleep will not be disturbed. Persistence along this line is usually rewarded with success.

Dr. Thomas S. Southworth, New York: Aside from the fact that breast milk is more readily digested, it has always seemed to me that one of the reasons children do so much better on breast milk is that the average child at the breast requires less supervision than a child on the bottle. Bottle feeding must be constantly changed and modified in order to adapt cow's milk to the child's needs during its first year. Nature does what adapting is necessary in the breast milk. I do not, however, consider that the breast fed child should be allowed to go without proper supervision on the part of the physician, and I believe that a great many of the failures to nurse successfully are due to the fact that the mothers are left to their own resources. I am glad Dr. Griffith used the expression "awakened conscience of the physician." Others have spoken here of the fact that we as physicians have been largely responsible for the decadence of maternal nursing. It is my experience that the man who readily advises a mother to wean her baby and put it on artificial feeding is, as a rule, an unsuccessful artificial feeder.

I am a little afraid that someone might misunderstand Dr. McClanahan when he quoted me as saying that "either the breast milk comes in abundantly and is good, or it comes in scantily and is bad." That is the popular opinion, giving rise to the opinion that if the milk is abundant and good one can continue with it, and if it is scant and bad one must stop it. The latter is not my deduction. I do not believe that there is very much bad breast milk; there is scanty milk, and sometimes it is lacking in a sufficient quantity of fat. When a mother tells me that her child has been removed from the breast because it was having green stools and the doctor said her milk was poisoning it, I know that that doctor was on the wrong track. There are instances when the maternal milk is poisonous, but they are extremely rare. I do not care much about elaborate examinations of the breast milk. I use the Holt apparatus chiefly to find the amount of fat, but we can be misled by the analyses of the milk. I think that we should pay less attention to analysis and more attention to building up of the general health of the mother, and [illegible] the quality of the milk usually takes care of itself. I think that if we increase the m[illegible] more than one or two daily [illegible] stimulation of the breast and [illegible] this reason I then have the child nurse at both breasts during each nursing.

As Dr. McClanahan said concerning his cases of pertussis, through which several children passed successfully, breast feeding is one of the greatest protections to the child, not so much in making it less liable to infectious disease as in enabling it to withstand infections.

Dr. Henry L. K. Shaw, Albany, N. Y.: Those of us who have had experience in institutional feeding find that many lives are saved by simply giving one breast feeding in twenty-four hours. At the Infants' Hospital, with which I am associated, the board of managers authorized the employment of two wet nurses. Five or six babies are often nursed by one wet nurse, who gives each baby one or more nursings in the twenty-four hours and the results are marvelous.

The benefits of nursing the baby for a certain time and then finishing with a bottle feeding have been brought clearly before the profession by Dr. Southworth. He coined the term "complemental feeding" when the breast is followed by the bottle. When the entire breast feeding is replaced by bottle feeding, the term "supplemental feeding" is employed.

I want to protest against Dr. McClanahan's statement that the breast pump does not stimulate the breast. A concrete case will illustrate what I mean. About four weeks ago a mother brought her baby to my office with the following history: The baby was 5 weeks old and had been exclusively breast fed for two weeks. Since then she had been fed on several formulas and prepared foods and had lost in weight. The mother had plenty of milk but because the baby had colic she had been told to wean it by her physician. She still had plenty of milk and used the breast pump once or twice a day to relieve herself. Analysis of the milk showed practically no fat. She was ordered to stimulate the excretion of milk by pumping regularly every two hours and massaging the breast. In a week there was 2.5 per cent. of fat and a few days ago it was over 3 per cent. The baby is now nursing regularly and gaining although it is having two supplemental feedings of modified milk.

Dr. Frank S. Churchill, Chicago: At the Children's Memorial Hospital in Chicago we always keep one wet nurse throughout the summer months two wet nurses. The results are much better with them than without. We do not feed one particular baby with breast milk but get as much breast milk as we can and divide it up among the different babies, giving to each baby perhaps one, two or three feedings in the twenty-four hours; the other feedings are of modified cow's milk. We all know that if a baby has ever so small an amount of breast milk during the twenty-four hours, it can take a higher percentage of the elements of cow's milk than when on cow's milk alone. Our experience has been that the breast pump is very stimulating to the breasts of these nurses, and with it we get large amounts of milk. That and the regular hygienic life which the nurses lead give very satisfactory results. They come in giving as a rule small amounts. They are put on a regular diet, lead an almost perfect hygienic life and the result is a great improvement in their general condition. We do not believe it is fair to a wet nurse to put to her breast the babies in the hospital because we never know how many of those may have congenital syphilis, so we have the breast milk pumped out and fed to the baby. This apparently has a very stimulating effect. The woman soon begins to secrete much more milk than on entering the hospital and in some instances marvelous amounts are secured. Our maximum amount was secured from a wet nurse, a primipara, who gave during the twenty-four hours for a matter of several weeks 5 quarts of milk a day. You may ask how we know. By the method I have just detailed it is quite possible to know exactly the amount of milk we are feeding our babies in the ward. We were feeding to those babies a little over 4 quarts of milk in twenty-four hours. The wet nurse was in addition nursing her own baby. I had that baby weighed before and after nursing for quite a number of times in order to get the average amount. That totaled to a little over a quart.

Dr. Collins H. Johnston, Grand Rapids, Mich.: We often find difficulty in getting wet nurses. Being near Chicago we can sometimes get one there. Last summer we saved the lives of a number of babies by securing a woman who could spare 8 or 10 ounces or a pint of breast milk a day. In hot weather this is a great boon to the babies.

Several of the speakers have referred to the fact that wet-nursed infants are stronger and more vigorous at the end of the first year of life than the bottle-fed babies. Last summer while in Berlin I learned of the results of an investigation along this line which are exceedingly interesting. The investigation included 176 families. Twenty-four of these families with 100 children all breast fed at the end of five years of married life had lost no children, while every one of thirty-three families whose children were all bottle fed at the end of five years had lost one or more children. The results were especially interesting in families in which some of the children were breast fed and some bottle fed. In one group of twenty-nine families with eighty-five breast-fed children and 100 bottle-fed children, at the end of eleven years all of the breast-fed children were alive while 57 per cent. of the bottle-fed babies were dead. In another group of thirteen families with forty-eight breast-fed and twenty-three bottle-fed babies, the former were all alive and healthy while the bottle-fed babies were all dead.

Dr. George D. Scott, New York: It is very interesting to know the conditions which underlie breast feeding and bottle feeding. Those of us who have seen the peasant women of Europe, particularly in the southern part, feed their children any place by simply exposing their breasts and nursing the child and who have seen our own women try hard to nurse their children without being able to, will see the condition underlying this whole question of bottle feeding. Those of us who try to use the bottle a great deal, who try to give food and find it inadequate, cannot help feeling that breast feeding is at all times the best. The underlying cause or condition is psychic. If you go into the psychic condition of a woman's mind, if you let her know that her child can be bottle fed without any responsibility to her and no exertion on her part and no self-denial in food and social pleasures, you will be obliged to put that child on the bottle. If, however, on the other hand you make that woman feel and instil into her mind the fact that breast feeding is best and that bottle feeding is only supplemental to breast feeding, you will, I think, make her try harder to nurse her child. Those of us who work among the poor and lowly, I think, have tried hard to make mothers feed their own children, with more or less success. By encouraging bottle feeding we do humanity great harm.

I want to make a protest against the attitude of the obstetricians, who think they can feed the child maybe from birth. They feed it sometimes for two or three months, and when the baby is in a poor condition they throw it on us. I object to the obstetrician feeding children over one or two weeks. I think then only the pediatrist should control them.

Dr. T. J. Harrington, Milwaukee, Wis.: It seems to those of us who do not spend all our time on diseases of children that a most important question has arisen. Two of the speakers have referred to supplemental feeding. They put the child first on one breast and then on the other, and if necessary give the child the bottle in addition. The point is to find out in what way we can have the mother give the greatest portion of the necessary food in order that the child may gain constantly and steadily. It is a question of how we can get the best work from the mammary gland. It seems to me from my study of the matter that it is a mistake to put the child first on one breast and then on the other and then on the bottle, because you do not give the mammary gland the best chance to do its work. A healthy mother who has sufficient milk for her child nurses first on one breast and then on the other, giving each gland a rest of from four to six hours. Yet you would take a mother who has a limited supply and tease out a small amount from each mammary gland and only give each gland a rest of from two and a half to three hours. I believe that the best results will be obtained, and that supplemental feeding will be at the lowest amount if the mother nurses from only one breast at a time, giving each breast a considerable rest in order that it may attain its highest physiologic power, allowing the child to nurse for from ten to fifteen minutes, then after that and in addition, put the child on the bottle if necessary I say after and not before, because if you put the child on the bottle before, you are not in a position to take advantage of the increasing quantity of milk which that breast may be secreting if you are managing the case correctly and giving the mother proper rest and nourishment

Dr **Charles Douglas**, Detroit It seems to me that the impression has been left that every woman can nurse successfully if we only manage her properly There are certain conditions under which it is impossible to do successful nursing It is not the putting of a certain amount of liquid into a child's stomach that makes success You must have a successful result. Some women cannot nurse successfully no matter what they do They have milk, but it does not produce a good effect on the child What can we do with such a patient? Regulate her diet and give her rest, which is an absolute necessity After this is done and we find that the child still has green, ropy stools, I contend that it is an error and an injury to persist in giving even one or two feedings of that milk in each twenty four hours I am heartily in accord with all the recommendations for giving one feeding when it can be done properly It is nonsense to talk of giving a child breast milk simply because the mother produces it We must know that what we are getting from that mother is right She must have good nourishment, rest, a limited amount of labor, etc to give a good secretion If then the milk fails to produce a good yellow stool, I think that mother's milk should be laid aside and the child put on modified milk. One feeding a day of mother's milk, when it is the right quality, no matter how small, is beyond price There is nothing we can purchase which approaches it in value to the infant

Obstetricians certainly have been doing a great deal of careless work in caring for infants I will go a step further also and say that we are responsible in a large measure for the crude, negligent work being done by midwives and the harm that results Our attention should be directed toward making midwives more efficient, so that they can do better work

Dr **Francis P Denny**, Brookline, Mass There is one argument in favor of supplemental feeding which Dr McClanahan did not mention and that is the advantage to the child of starting cow's milk early and gradually, thus accustoming it to the albumin of the cow If a child has to be weaned suddenly, that child is in a better condition to be weaned if for months it has been having at least one bottle of cow's milk a day

Dr **John Zahorsky**, St Louis, Mo I think it is wrong to condemn physicians generally Most physicians do try to keep the baby on the breast, but there are a great many conditions about breast feeding which, unfortunately, we do not understand, and we might just as well admit it now In the first place, we have the condition of dyspepsia of young infants The baby has bad stools, continued flatulence gets colic as soon as it nurses a drop from the mother and screams day and night The dyspepsia in young infants is attributed to various causes, bacteria, underfeeding, overfeeding, and what not. The truth of the matter is that we know nothing about it It is not too high fat or too high proteid because in many cases which I have attended at least to my own satisfaction I have not found excessive fat or excessive proteid Disturbances in a young infant will often lead the mother to put the baby on the bottle because the baby is suffering and we cannot relieve it Diminished milk supply is the case in a great many healthy well to do mothers They try to nurse their children, but they have not enough milk Some mothers of fine healthy appearance give only 1 or 2 ounces of milk and they are not able to increase the quantity after trying in every way Another reason why some women do not nurse their babies is a painful sensation when nursing This may come from infected breasts Quite a large percentage are due to this cause How can we prevent sore nipples? Then there are some mothers who have a disagreeable sensation when nursing the baby I think there is a definite pathologic condition in these cases, and they should be studied

We say 'Keep them on the breast," but as a matter of fact we all give the bottle very soon We either replace the breast feeding or add to it We have to for if we did not the other doctor across the street would

Dr **Jules M Brady** St Louis It should be emphasized here that it is not always a paucity of the natural food which leads to artificial feeding Many infants sicken as the result of overfeeding on the breast The condition is not correctly interpreted and as a result artificial feeding is instituted

SOME CASES OF HYSTERIA PRESENTING SYMPTOMS USUALLY FOUND ONLY IN ORGANIC DISEASES *

BEVERLEY R TUCKER MD
Professor of Nervous and Mental Diseases Medical College of Virginia Neurologist to the City Hospital Memorial Hospital
and Johnston Willis Sanatorium Richmond Va
and State Epileptic Colony Lynchburg Va

RICHMOND VA

In the presentation of a paper with this title I fully realize that I am treading on dangerous ground The subject is of great importance however in that distinguished and trained neurologists have differed for instance as to whether the Babinski phenomenon absent knee-jerks incontinence of urine and feces ankle-clonus and other usual signs of organic disease are ever found in hysteria

In remarking on this I shall only quote a few statements gathered here and there from the literature on the subject Mills[1] thinks that true astereognosis loss of the sense of position true ataxia and hemianopia are not found in hysteria Purves Stewart[2] states that in hysteria absent knee-jerks incontinence of bladder and rectum and the Babinski phenomenon never occur Babinski himself says that hysteria itself is incapable of modifying tendon-reflexes Dana[3] says that the sphincters are never involved except temporarily or through some complication Incontinence of feces never occurs, according to Grainger and Stewart[4] Philip Coombs Knapp[5] gives an excellent biography of the reflexes in hysteria and says that the Babinski and Oppenheim reflexes are never caused by hysteria Tendon-reflexes may be exaggerated within normal limits Whether hysteria can give rise to ankle clonus or loss of knee jerks is doubtful Knapp also says that total paralysis and total anesthesia on one side are very rare He says that Crocq[6] believed he had found ankle clonus and patella-clonus in hysteria and was supported by Charcot Sachs Oppenheim and others and loss of knee jerks has been found by Steiner, Marie Nonne Wigand and Charcot Complete absence of plantar reflexes has been noted by Knapp and other observers Mills[1] states that Van Gehuchten has reported one case with the Babinski phenomenon and ankle clonus which disappeared in a few days In commenting on this he says 'One case however striking is not sufficient to contravene the testimony of scores of other well studied cases

The whole outcome of a case may thus hinge on the view we take of one or more of the signs or symptom found Hysteria, indeed, is a disease which has caused so much controversy that it is our duty to clarify our conception of it as much as possible As in neurasthenia, the present-day methods have done much to lessen the frequency of the diagnosis of hysteria by the neurologist Since we have recognized and classified dementia praecox, manic-depressive insanity, the anxiety psychoses, psycholepsy and others, we have fortunately narrowed the conception of hysteria

The cases to be mentioned here are not reported in full because this is deemed unnecessary and would add too much to the length of the paper These cases were frankly hysterical however, as careful examination and subsequent observation proved

CASE 1 —*Hysteria with Pseudo Aphasia* —The patient was a mulatto woman about 55 years of age a member of a neurotic family The patient gave the history of frequent hysteric seizures during the course of her life from puberty In October 1908 on the anniversary of her wedding day, she was taken with a right hemiplegia without facial involvement and without unconsciousness It was accompanied, however, with great difficulty and slowness in speech There were areas of analgesia and anesthesia on the right leg and neither the right leg nor the right arm could be moved voluntarily Slight pressure over the left ovary made her flex her right knee about 45 degrees and the right arm about 90 degrees to the great surprise of her family By one treatment with a strong faradic current she was made to talk better, to put the right hand to her face and to walk She shortly recovered Investigation developed that the patient's husband nine months before had a cerebral hemorrhage with paralysis of the right side and aphasia and had died after a short illness The onset of the patient's symptoms resembled exactly those of the husband except that she was not completely unconscious The interesting point about this case is the hysterical hemiplegia with a pseudo aphasia which complicated the picture

CASE 2 —*Hysteria with Temporary Loss of Sphincter Control* —The patient a young white woman aged 17, was seen during November 1907 This patient had been married when 13 years of age, borne a child when 14 and had used quinin to produce abortion of a 5 months fetus three months before she came under observation She was emaciated to such a degree as to suggest progressive muscular atrophy Her hands had a claw like appearance at first but she could move all of her fingers normally There was marked contraction of the lower extremities especially at the knees Careful examination for organic signs or symptoms was negative Areas of anesthesia were found on the left upper extremity The patient appeared so ill that no eye examination was attempted at this time except that the pupil reflexes were found normal For a few days the patient voided urine and feces involuntarily With careful nursing she gained flesh and with massage and stretching her limbs were straightened She had no further trouble with incontinence and in a few months was well and at home doing her usual housekeeping To determine if spinal anemia accounted for the loss of sphincter control a blood examination was made which was negative The patient's hemoglobin was 62 per cent and her red cell count was 4,500 000 The interesting point about this case is that the patient had incontinence of urine and feces without blood changes or other signs or symptoms of organic disease The regain of sphincter control was permanent The loss was due evidently to simple but great functional body weakness

CASE 3 —*Unilateral Hysteric Amblyopia* —The patient, a white girl aged 16, seen Sept 9 1909 developed hysteria, owing it was thought to overwork at school and a love affair She complained of not having been able to see out of the right eye for a week past Dr John P Davidson made an ophthalmoscopic examination and diagnosed unilateral hysteric amblyopia Hysteria was confirmed by the history of hysteric seizures, [illegible] and pseudoclonus By suggestion she was made to read large type with this eye the first day, medium type the second day and small type the third day after which she had no further trouble The interesting point about this case is, of course, that the amblyopia was unilateral

CASE 4 —*Hysteria in Which the Knee-Jerks Were Absent* —The patient in this, the last and most important case to be mentioned, was a young married white woman, aged 19, seen during July 1909 She had given birth to a healthy child six weeks before Her marriage was a runaway match with a man who drank to excess and who treated her with extreme cruelty The patient had just separated from her husband She gave the history of infrequent hysteric seizures in the past Two weeks before she was seen she had been paralyzed in the right arm When first seen she had loss of power in the right leg, having suddenly regained power in the right arm Examination showed contracted vision fields, complete anesthesia of the right leg from the hip down including the foot, and areas of anesthesia on the left leg and also over the back Hoover's sign showed the paralysis of the right leg to be hysteric in type There was, however, absolute loss of both knee jerks both without and with reenforcement Believing the case one of hysteria, and not being willing to give up the diagnosis on this symptom, I tested the knee jerks of the patient's mother and found them absolutely absent, even with reenforcement The mother, who gave no other symptom of brain or cord disturbance, stated that seven years previous she had been told at Johns Hopkins that her knee jerks were absent The patient's sister, aged 11, was tested and found to have knee jerks A first cousin on the maternal side, aged 7, was then tested and knee jerks were found to be absent even on reenforcement No other members of the family could be tested

The diagnosis of hysteria was made, and with suggestion and several faradic shocks the patient was made to walk The anesthesia cleared up within six days and the patient has remained well This case is interesting because the absence of knee jerks was accounted for as a familial phenomenon and was in all probability congenital

Other less striking cases could be mentioned, but these are possibly sufficient to illustrate the point

The above cases are given in brief outline, not with the intention of trying to prove that in hysteria organic signs and symptoms may occur as part of the symptom-complex and manifestations of the disease *per se*, but to call attention to the fact that definite or apparent organic symptoms may occur as a complication To illustrate A beautiful piece of tapestry was recently found by an art-buyer which appeared genuine and old, except that the general picture was complicated by glass beads being inserted in the representation of a piece of jewelry where diamonds should have been embroidered The piece was rejected Later it was found by closer observation that these glass beads had been sewed on by a child over the embroidered diamonds and the piece was thus proved genuine and was sold at a great price The picture of hysteria may be genuine with an incongruous symptom inserted and if this symptom is not thoroughly investigated and taken out of the picture we are liable to reject the case and believe it not genuinely hysteric.

208 East Franklin Street

Whooping Cough —Any disease which kills 10 000 children per annum is a serious one If bubonic plague were to kill that many children in the United States in one year, the whole world would quarantine against our country A child dead of whooping cough is just as dead as a child dead of plague A child, whose body is weakened by disease is a potential economic loss to the nation Whooping cough is a danger to be avoided and combated in the interest of humanity and the citizens of to morrow —W C Rucker in *Pub Health Rep*

THE RECIPROCAL INFLUENCES OF MORBID CONDITIONS OF THE MOUTH, JAWS AND GENERAL ECONOMY*

M. I. SCHAMBERG, D.D.S., M.D.
NEW YORK

Much has been written in recent years relative to the unhygienic mouth as an etiologic factor in systemic disease. In fact, a wave of enthusiasm has been created so that oral cleanliness as a prophylactic measure against disease is receiving earnest attention both here and abroad. The municipal appointment of dental examiners in the public schools, in many parts of this and other countries, is evidence of the interest that has been manifested in the care of the mouth and teeth. Great credit is due the dental profession for this important step in the right direction, for its members have been mainly instrumental in bringing it about. The medical profession has likewise been a factor in proving to city officials the need for this advance in the protection of public health.

There is, however, much to be done to establish in medical, dental and lay minds a knowledge of the tremendous bearing that certain mouth and jaw diseases have on the general health and, furthermore, the manner in which many disorders can be early detected by a careful examination of the mouth. I will not dwell on the fact that many persons are rendered more susceptible to disease by the lowered vital resistance created by tooth, mouth and jaw troubles. This is too evident to all who give the matter any thought, but I want to lay stress on the frequency with which patients under treatment for mouth troubles are permanently cured of deviations from the normal which originally appeared to have no relation to the local lesion within the oral cavity. It is equally true that many systemic disorders are either directly or indirectly responsible for morbid conditions of the mouth and jaws.

The time-worn custom of physicians of asking to see the patient's tongue is indicative of the manner in which the oral mucous membrane in its varying condition of health and disease reflects primarily the state of the alimentary tract, secondly, the presence or absence of febrile conditions and, thirdly, circulatory changes. In certain maladies, examples of which are scarlet fever and syphilis, the tongue may exhibit as definite indications of the disease as are found in other parts of the body. In cerebral, meningeal and nervous disorders the tongue may again give enlightenment and thus be a prompt means of arriving at an accurate diagnosis. During convalescence from many diseases and in fact when the patient's life is in the balance between death and recovery, the tongue, if its readings are properly interpreted may aid in encouraging the family or preparing them for the worst. So the tongue during the course of disease may materially aid in determining the prognosis.

The lips of the patient are occasionally studied by careful and observant diagnosticians mainly however to note conditions of impoverished blood or types of anemia, as is the everted eyelid for the study of the conjunctival lining. Occasionally a definite lesion on these parts may be sufficiently evident to attract attention.

How very unusual is it however, for physicians to make careful observations into the conditions of the mouth as a whole, to determine the presence of lesions on the mucous surface of the cheek, the floor of the mouth beneath the tongue, the palate, the gingival margins of the gum, or the roof and floor of the vestibule of the mouth. These parts to the stomatologists impart even greater information at times than do the tongue or lips. Just as does the dark line in lead-poisoning exhibit itself, so do other changes in peripheral circulation leave their mark. Faulty metabolism, auto-intoxication, rheumatism, gout, anemia, diabetes, renal, cardiac and pulmonary diseases all show their ill effects on the gingival border of the mucous membrane and often before symptoms are sufficiently pronounced in other parts to cause the patient to consult a physician.

It is no unusual occurrence in my practice and no doubt my experience conforms to that of many who specialize in the treatment of diseases of the mouth, for me to refer to the family physician patients who on examination of the mouth are found to be in the incipient stage of one of the many maladies aforementioned. Indeed, I have occasionally found a patient to be in the throes of a well-advanced illness of no trivial character. In several instances, the true cause of what appeared to be an ulcerative or gangrenous stomatitis was recognized as the dreaded oral manifestation of leukemia only after I had insisted on a blood examination.

The vast majority of oral and even dental disturbances are markedly influenced by the state of the general health of the patient. In such extreme instances as osteomalacia, rachitis, and even the normal process of pregnancy do the mouth and teeth suffer with the rest of the system the drain on the osseous structures. In most diseases of the dermal covering of the body the prototypes of their lesions can be seen within the mouth, and here, owing to their modified appearances great mistakes may be made in diagnosis.

All that has been said about the influence of systemic disease on the tissues of the mouth is more generally conceded and accepted by medical practitioners than by some of the excessively enthusiastic dental men who claim to cure all forms of so called pyorrhea or suppurative gingivitis by local treatment and local treatment alone. These men fail to realize that they are but maintaining a more hygienic and non-irritating influence on tissues which are rendered susceptible to inflammation and infection by a systemic trouble. Great good is accomplished by such treatment when a proper regard for the underlying cause is kept in mind. Woe to him, however, who attacks boldly by local treatment only a suppurative gingivitis of diabetic origin.

The reciprocal influence of abnormal conditions of the mouth and jaws on the general economy has not been accorded to date the importance that it must receive if the health and welfare of human kind is to be consistently conserved.

Briefly stated, the bearing that the mouth has on the general organism is governed first by the ability of the mouth to perform its normal functions and to contribute its share toward the intricate and marvelous method of providing nutriment to the animal system. A failure in any measure to live up to its contract is accompanied by disturbances further on in the process with associated efforts to counterbalance the evil. So then must other organs and parts suffer or assume responsibilities which will eventually tell on their longevity.

Second, the matter of provision of f [illegible] m through the natural avenue, the mouth [illegible] n-plished without contamination such as is prone to occur when the mouth is not kept mechanically clean, and by this is meant that all surfaces of the buccal mucous membrane and all surfaces of the teeth must be kept free from oral debris and the virile organisms that infest unclean mouths Third, such local infections as arise in spite of a reasonable amount of care must be met and conquered

---

* Read in the Section on Stomatology of the American Medical Association at the Sixty-Third Annual Session held at Atlantic City, June 1912.

Stress should be placed on the eradication of infective foci from the mouth, even though radical surgical procedures and the sacrifice of teeth become necessary Current literature, both medical and dental, contains many references to the relation of remote diseases to infections arising within the mouth Infective endocarditis, rheumatism, anemias and other affections of serious moment are occasionally laid to the door of mouth infection Many patients in my practice within recent years have exhibited decided attacks of neuritis involving the arm, shoulder and other parts that have cleared completely following the surgical removal of an infected area from the mouth Patients who are suffering from diabetes kidney troubles, etc which may have been the predisposing cause of gingival disturbances within the mouth, are usually improved when efficient treatment removes the pus which by absorption aggravates the systemic trouble

It is unnecessary for me to dwell further on the many and varied complications that may arise from septic absorption within the mouth

Another important field of study is that which relates to the reflex disturbances that arise as a result of dental and maxillary abnormalities The ear, the eye, the nose and throat, as well as parts further removed from the mouth, are occasionally the seat of baffling disturbances that are traced to conditions within the mouth Neurologists are beginning to realize that some of their cases of melancholia dementia præcox and other types of nervous disorder are occasionally brought on by an impacted tooth, a hidden abscess, or some other equally obscure trouble connected with the mouth and teeth I am seeing such cases with increased frequency and in most instances am able to record a decided improvement if not an absolute cure of the nervous or mental condition

At this time I will not report the cases that have come under my care for I will hope to supplement this brief communication with one which will be more clinical in its nature

Before closing I desire to make reference to a paper by Baker[1] in which he presents a compilation of diseases attributable to mouth conditions According to his list 125 different affections were traced by scientific men to dental and mouth disorders In studying the bibliography of Dr Baker's article, I find that almost all authors quoted are graduates of medicine I refer to this point as the strongest evidence toward the verification of their findings and that such reports were not made as the result of biased observations Though Dr Baker collected seventy nine articles written within the past ten or eleven years from which he culled the references to the large variety of diseases such sporadic outbursts of individual enthusiasm are scarcely adequate appeals for the betterment of the cause for which we are working The dental profession the medical profession and the lay public have begun to realize what scientific stomatology will contribute toward health preservation

ABSTRACT OF DISCUSSION

Dr. Joseph Head, Philadelphia There seems to be the general idea that it is extremely dangerous to treat diabetics who have pyorrhea I have in my own practice at present two patients suffering from diabetes, by injection of bifluorid solutions into the pockets I have been able with care and safety to scrape the roots clean and to get a fair amount of healing In fact, teeth which have been very loose at the start have steadily improved, and pus, which flowed from nearly all parts of the mouth, has almost entirely disappeared The discomfort which the patients experienced before they came to me has been relieved, and although they have not been cured, they are comfortable and I feel that there is every reason to believe that as time goes on they will perhaps continue to improve One of these two patients had a lower six year molar that could not be cured of the pus that flowed from around the anterior root I scraped the pocket out but that did not improve it The pulp was apparently healthy and normal, perhaps a little oversensitive, but it was only when I destroyed the pulp in that tooth that the pus ceased to form I have noticed frequently in pyorrhea that a pocket from which the pus could not be eradicated would not heal up until an apparently healthy pulp was destroyed It is easy to understand that the live pulp may be so infected with the overirritated peridental membrane that it may not be able to stand against the inroads of infection that tend to prolong the flowing of the pus around the pockets

Dr. Virgil Loeb, St Louis A great fault in the study of diseases of the mouth is the omission or failure of many men to make a thorough examination of the oral cavity Dr Schamberg confined his remarks in this respect to medical men, but I think he should have made it broader and included the dental men as well There are very few, I think, who take the time to make a thorough examination of the mucous membrane of the oral cavity, if this were done on every patient and only a single instance of the beginning of some malignant trouble were disclosed, it would be well worth while

Dr M I Schamberg, New York I referred to men who attempt to treat cases of pyorrhea in diabetic cases without any regard to the underlying cause I treat diabetic cases constantly and have often noticed after local treatment that there has been a diminution of glycosuria I approach these cases a great deal more cautiously than I do the so called simple cases Cases have been referred to me for treatment after men, some of them pyorrhea specialists have injured the patients materially by disregarding their systemic trouble I have had a number of cases in which the floor of the antrum had sloughed away as the result of pyorrheal treatment applied in diabetic cases

TEMPORARY TOXIC AMAUROSIS AND PARALYSIS FOLLOWING INJECTION OF ETHYL ALCOHOL INTO A CHRONIC EMPYEMA SINUS

Louis Friedman, M D, New York
Lecturer on Gynecology New York Polyclinic Medical School and Hospital Cystoscopist Harlem Hospital

Alcohol amaurosis is usually due to chronic intoxication following the abuse of distilled and malt liquors

Acute alcohol amaurosis is comparatively rare but even in these so called acute cases total or partial blindness has followed when whisky in excess has been drunk for several weeks Methyl alcohol taken in toxic dose has produced blindness within twenty four hours De Schweinitz[1] says

'In so far as the visual effects are concerned the acute cases may be dismissed with comparatively short notice inasmuch as except in rare instances the visual phenomena are of temporary character and amblyopia if it occurs at all is *exceedingly uncommon The ocular symptoms consist chiefly* in paresis of one or other of the external ocular muscles Now and then acute alcoholism seems to have been responsible for almost complete blindness without ophthalmoscopic change, rapidly disappearing under antiphlogistic treatment and total abstinence."

---

[1] *De Schweinitz, G L Toxic Amblyopia* 1896 p [illegible]

I have been unable to find any record of pure ethyl alcohol amaurosis. The following case therefore presents features of sufficient interest to make it worth reporting. It was a case of acute amaurosis which occurred immediately after the absorption of 90 per cent. ethyl alcohol, the mode of entrance was the injection of about 25 c.c. of pure alcohol into a chronic empyema sinus through a cannula introduced into the sinus, the amaurosis was accompanied by temporary motor paralysis of both upper and lower extremities, and was followed by complete recovery.

The patient, I. S., aged 24, single, had always been well up to June 6, 1910, when he was operated on for gangrenous appendicitis. The wound was drained. Following this the patient developed a subphrenic abscess for which he was operated on July 8. One week afterward, symptoms of thoracic empyema appeared. July 15, 1910, a thoracotomy was performed, with drainage.

The appendix and subphrenic abscess wounds healed entirely, but a chronic empyema sinus developed, which was treated up to March 25, 1911, about ten months, without any sign of healing. There evidently was a communication between the sinus and the bronchus, because the first time I injected bismuth paste, the patient nearly choked in an effort to cough up and expectorate the bismuth paste which I injected. Repeatedly on the injection of bismuth paste although in smaller quantities injected slowly, he would cough and expectorate the bismuth.

This treatment lessened the discharge considerably for a while but eventually had to be given up since no benefit resulted. After the sinus narrowed down considerably I began to inject 95 per cent. ethyl alcohol into it, using a narrow cannula, and a 30 c.c. capacity syringe. The injections were repeated at each dressing without causing any untoward symptoms whatever until March 11, 1911, when, after I had injected the sinus with the alcohol, the patient without any warning slid off my table, landing on the floor in a perfectly limp condition. He was unconscious for a few seconds. Believing that he had fainted, I allowed him to stay on the floor until he recovered consciousness, when I asked him to help himself back to the table, but he replied that he was unable to move his legs. I picked him up and placed him on the table, when he assured me that he felt all right but that he could not see me. Absolute flaccid paralysis also was present in both upper and lower extremities. His mind was clear, speech normal, skin and lips normal in color, no cyanosis, pupils were moderately dilated and reacted to light. The patient was unable to see me or any object held up to him, but was able to distinguish light from darkness. Respiration was somewhat rapid and sighing; the patient was unable to move or lift either upper or lower extremities. This condition lasted about twenty minutes.

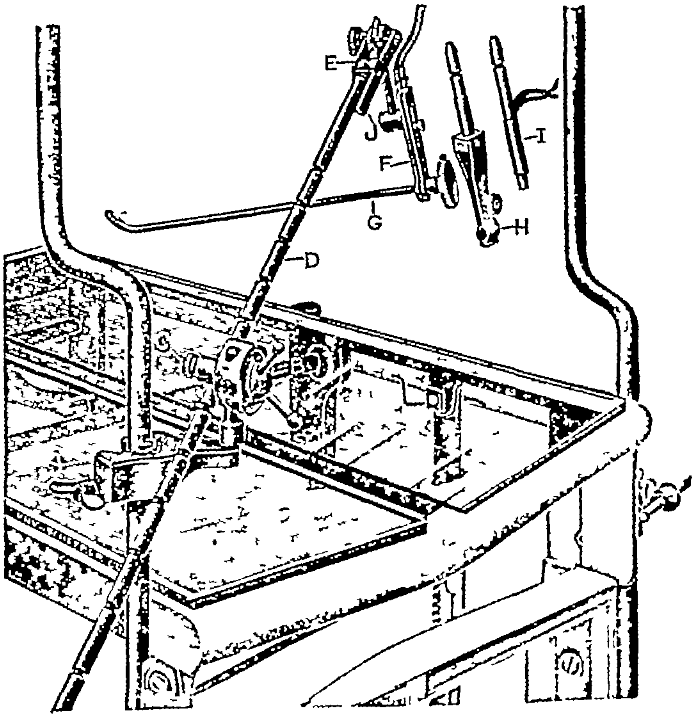
Cutaneous sensation was present. The patellar reflexes were exaggerated. Gradually the patient regained control of his extremities, first his legs, then his arms, accompanied by incoordination, that is, if I asked him to lift his leg he would do so in a jerky, uncertain, draggy fashion, then he would lose control again, the limb falling down entirely limp; or in attempting to lift his arm he could not without simultaneously attempting to lift his leg as well. Muscle resistance was absent at the beginning but gradually returned in both upper and lower extremities. The patient stated that no matter how hard he tried he could not move or control his limbs. In about half an hour all signs of motor paralysis disappeared, and he could move and control his extremities as well as ever, walking without assistance. Complete amaurosis was present for about one hour but gradually his sight returned so that four hours after the accident he was able to distinguish objects and shapes fairly well. Perfect vision was regained in about three days. A competent oculist examined his eyes half an hour after the accident, a slight congestion of the fundus was present. No other ophthalmoscopic change was noted. A month following I did a subperiosteal resection of portions of five ribs; the patient had a rather stormy convalescence but eventually recovered with absolute cure of his empyema sinus.

202 West One Hundred and Thirteenth Street.

CYSTOSCOPE HOLDER

Henry Dawson Furniss, M.D., New York
Assistant Attending Gynecologist, New York Post-Graduate Hospital and New York Red Cross Hospital

In teaching cystoscopy in women the inability to hold steady the long male cystoscope so that demonstrations could be given the students led to the use of shorter instruments. These had some objections, among which was the fact that they are made in few of the different types, so a holder that would allow free manipulation of the cystoscope and that could be fixed in any desired position was a welcome device. I feel that the instrument here presented, which embodies many improvements suggested by use, serves all the purposes for which a holder is desired.



Cystoscope holder

A is a removable piece designed to fit a leg holder of any size from ¼ inch to ¾ inch. On the projection is a short rod over which slips B, this allowing easy removal of the holder proper. B is so designed that it allows an up and down, a circular and a twisting motion of the long rod D. All of these motions can be locked by the large wing nut on B. C is a screw that projects into the slots on the long rod D, thus preventing lengthwise motion after adjustment of length for the particular table on which it is to be used; there is seldom any necessity for a change. The portion F is insulated from D by fiber washers and thus short circuiting is prevented. On the distal end of the spring J is a pin that projects into the slot cut in the piece that is directly connected to the cystoscope; this prevents slipping and allows rotary motion. These pieces are made for all cystoscopes with a rotary contact. J is for the Continental type, I for Wappler instruments. H is a universal holder clamping around the cystoscope shaft. J and I also serve as electric connections. Examinations are made with the cystoscope attached to the holder. With most other holders, attachment is made after locating the part to be seen.

The advantages of using such an instrument are that the teacher can demonstrate to the student any part of the bladder, and also the student can leave the instrument in position to show that concerning which he wishes instruction The instrument holds the cystoscope in any desired position for any length of time If for any reason the examiner is interrupted and has to leave the table, it is not necessary to withdraw the cystoscope or to have some one else hold it, he has only to tighten the nut on B and the one on E Where ureteral catheters are to be left in for any length of time, for the collecting of urine or washing out the renal pelvis, this instrument is of the greatest assistance

For five months I have been using it not only in private, but more especially in teaching which it has made immensely easier I now regard it as almost indispensable

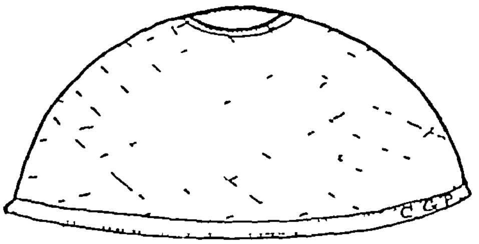
393 West End Avenue

AN ETHER MASK COVER

Carl G Parsons, M.D., Denver

The accompanying illustration represents a cover which I have devised for a drop ether mask It is made by quilting cotton between two layers of No 2 gauze cutting a hole 1½ inches in diameter in the summit, taking out one or two wedge shaped pieces at the base so as to cause the cover to fit the mask and hemming all raw surfaces with tape

The ordinary ether mask is covered with a few layers of gauze Ether is given by the drop method slowly at first and as soon as the patient becomes accustomed to the vapor, the above described arrangement is fitted over the mask with the base carefully approximated to the patient's face and the drug is then dropped onto the gauze through the aperture By this method patients are put under and kept under the anesthetic with a minimum amount of drug the anesthesia is much more uniform and there is no need of winding roller gauze or a cumbersome towel about the mask. The cover can be applied or removed in an instant After each administration the cover should be washed and dried



Ether mask cover

PENETRATING ABDOMINAL WALL WOUND BY REVOLVER BULLET COMPLICATED BY TWENTY TWO INTESTINAL PERFORATIONS, OPERATION AND RECOVERY

A Brigham Keyes M D Chicago

Professor of Gynecology Chicago Polyclinic Assistant Professor of Gynecology Rush Medical College Surgeon to Cook County Hospital

History—C P an Austrian aged [illegible] a machinist was admitted to my surgical service in Cook County Hospital, April 27 1908 with a history of having been shot about a half hour previously The bullet had been fired by a man somewhat taller than himself who was standing to the left and somewhat behind him The external wound apparently bled but little neither had there been any coughing vomiting or passage of blood from the rectum or bladder Comparatively slight pain was complained of in the abdomen itself but there was intense pain in the perineum and in the left side of the scrotum

Examination—The abdomen was slightly distended and there was [illegible] especially on the left side The absolute liver dulness was lost. A small oval dime sized wound was found in the left midaxillary line, on a level with the umbilicus, presumably the place of entrance of the bullet. The left side of the scrotum was somewhat discolored and very tender

Operation—Under ether anesthesia a median incision 10 cm in length, extending from midway to the ensiform downward to the left of the umbilicus to a point midway between this and the pubes was made. The abdominal cavity contained a slight quantity of fluid feces with much clotted blood and probably some bile The first part of the jejunum examined showed eleven intestinal perforations, several were also found in the mesentery Five of the intestinal perforations were closed with fine chromicized catgut and about 10 inches of another loop with six perforations and a badly injured mesentery and blood vessels were exsected and a Murphy button inserted and doubly stitched with Lembert's sutures Eleven more perforations were later found and sutured with fine catgut by Czerny Lembert sutures No more perforations being discoverable, the peritoneal cavity and intestines were carefully sponged clean with moist compresses wrung out of normal salt solution, the parietal peritoneum was closed with continuous catgut sutures, the recti fascia and skin with interrupted silkworm gut sutures and the wounds dressed No drain was inserted The patient showed signs of shock and anemia from loss of blood but responded to a hypodermic of strychnin sulphate, one fifteenth grain Four hours after the shooting, he was put to bed in fair condition with weak but regular pulse and thoracic respiration

Some interesting injuries caused by the ball noticed during the operation and in the exsected loop are shown in the diagram

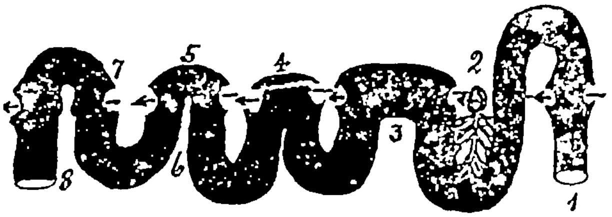


Diagram of peculiar injuries by bullet (1) perforation of the bowel from side to side (2) perforation of both layers of the mesentery cutting the blood vessels (3) perforation of a bowel loop at its apex (4) perforation near apex of small loop (5) perforation at apex in a sharply bent loop (6) intramesenteric perforation (7 and 8) entrance of the ball lower in a loop of bowel intramesenteric exit and reentrance and final exit on a free surface of bowel

Postoperative History—An enema of glycerin and olive oil administered on the evening of the third day was expelled with some flatus and liquid fecal matter The abdominal silkworm gut sutures were removed on the fourteenth day, the wound having healed by primary intention A fifteenth day radiograph showed the Murphy button in the left inguinal region probably in the sigmoid A pelvic radiograph on the seventeenth day failed to show the button, but revealed a 32 caliber bullet lying superficially just over the external inguinal ring which was removed without anesthesia Two subsequent radiographs also failed to reveal the button which had evidently been passed unnoticed by the patient (who was now permitted to go to the closet) on about the sixteenth day The patient was discharged (May 24 1908) on the twenty seventh day as cured May 1911 three years later I exhibited this patient before the members of the Chicago Medical Society (North Side branch) in a condition of perfect health He works as a machinist can lift 150 pounds and has neither disturbance of digestion nor pain The abdominal wound is entirely devoid of any signs of hernia

When asked as to how long before the shooting he had had his last meal he stated that ten minutes before the shooting he had eaten a cheese sandwich and drunk two bottles of beer

Beyond the interest the recovery has despite the large number of intestinal perforations there is the fact that the radiograph showing the bullet over the external ring might well have been misleading causing at least an unfortunate delay, in the belief that the bullet had only contoured the abdominal wall

In conclusion I wish to thank Drs R J Pickard, E B Rogers, J R. Kauffman and R. C Menzies, interns, for their able assistance

122 South Michigan Boulevard.

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLE HAS BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION ITS ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES"

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH *THE RULES ADOPTED BY THE COUNCIL.*

W A. PUCKNER, SECRETARY

AFRIDOL—Afridol is sodium hydroxymercuric toluylate, $C_6H_3(CH_3)(COONa)HgOH$, 2 3 1

Afridol is an odorless tasteless white powder, difficultly soluble in neutral or acid media but soluble in ammoniacal solution containing ammonium chloride Filtered aqueous solutions of afridol remain unchanged on the addition of ammonium sulphide solution or albumin solutions

If afridol be boiled with hydrochloric acid, an odor of benzoic acid is produced and the cooled solution when saturated with hydrogen sulphide yields a black precipitate of mercuric sulphide

Actions and Uses—It is said to be of value for disinfection of the hands in surgical and obstetric work and for disinfection of various other parts of the body, as well as of instruments and other objects It has also been recommended in the treatment of parasitic diseases of the skin and scalp, such as favus, acne, sycosis and seborrhea

Dosage—Marketed only as Afridol Soap (see below)

Manufactured by Farbenfabriken vorm Friedr Bayer Leverkusen Germany (Farbenfabriken of Elberfeld Co New York) U S patent applied for U S trademark No 81 387

Afridol Soap—Afridol soap is a soap containing afridol 4 per cent.

If an aqueous solution of afridol soap be treated with either ammonium sulphide or albumin solution no precipitate should be formed If an aqueous solution of afridol soap be boiled with hydrochloric acid and the solution made alkaline with ammonium hydroxide the addition of ammonium sulphide solution should yield a black precipitate of mercuric sulphide

Actions and Uses—(See Afridol)

Dosage—Afridol soap is used in the same way as any other soap For the prevention of boils the foam is generally allowed to dry or to remain on for at least ten minutes and then washed off

Therapeutics

DISTURBANCES OF THE HEART

(Continued from page [illegible])

TREATMENT OF ENDOCARDITIS

As mild endocarditis rarely occurs primarily but is almost always secondary to some acute disease, its immediate treatment is only a slight modification of that of the disease that is causing it A complication that is so frequent should always be expected and consequently warded off or prevented, if possible Knowledge of the diseases that most likely cause endocarditis makes frequent heart examinations a necessity to note when it arrives While an extra heart tire sleeplessness, the circulation of unnecessary toxins from a bad condition of the bowels and from improperly selected food all make this complication more likely, its occurrence is, nevertheless, often unpreventable

The most efficacious preventive measures are sleep, rest absence of pain prevention of exertion proper food that does not cause flatulence or other indigestion, good sufficient daily movements of the bowels, the prevention of intestinal distention, and maintenance of a clean moist surface of the body, produced by such sponging and bathing as the temperature demands

The disease having developed, the indications for treatment are really few, in fact, the treatment is mostly negative There is generally but little pain, the temperature from simple endocarditis alone is not high and the acute symptoms tend to abate

Local Treatment—Endocarditis having been diagnosed, especially if there is palpitation or pain, the ice-bag over the heart is often of considerable value but not so efficient as in pericarditis It often tends to quiet the heart, and may be of some value reflexly in slowing the inflammation If it causes restlessness however, and does not diminish, or perhaps in some instances increases, the pain it certainly should be stopped Children, in whom this complication so frequently occurs, generally do not bear the ice bag well Sometimes it may be advisable to substitute warm applications, and often a great deal of comfort is derived from them, the patient soon going to sleep One of the greatest values of either cold or hot applications is diminution of the discomfort from the cardiac disturbance, and the stopping of any pain that may be present If they do not do this, there is no object in using either cold or heat

The discomfort from blisters over the heart during the acute stage of endocarditis is greater than any good that they can do In adults a few small blisters may be used intermittently around the borders of the heart, after the acute symptoms are over, to act reflexly on the heart and possibly aid absorption of inflammatory products Sometimes improvement seems to follow such treatment, it certainly can do no harm

During convalescence the skin over the heart may be painted with iodin, repeated often enough to cause stimulation without injuring the skin, it seems at times to be of value Various iodin ointments or iodid ointments have been used, but they probably have no more value than the administration of small doses of iodid

Systemic Treatment—As this complication most frequently occurs during acute rheumatism, the question arises as to the value or harmfulness of salicylates and alkaline drugs With our recent better understanding of the action of pure salicylates on the heart (either natural or synthetic salicylic acid, which have been shown to act identically, if equally pure, we must believe that in any ordinary dosage they will injure the heart but rarely While salicylic acid will not prevent endocarditis it should be continued, if it is benefiting the arthritis In other words the indication for its use depends on its effect on the joints As it acts at times almost as a specific in rheumatism it would seem that it should be of value in the endocarditis caused by rheumatism On the other hand, the endocarditis occurs during the second or third week of acute rheumatism after the blood has been thoroughly saturated with salicylic acid Therefore it certainly does not tend to prevent rheumatic endocarditis hence for this complication alone salicylic acid is not indicated

Anything that tends to increase the acidity of the tissues and to diminish the alkalinity of the blood whether from starvation or other causes seems [illegible] produce endocardial and myocardial [illegible] if [illegible] inflammation Therefore in [illegible] that seems to be made worse by anything that increases the acidity, alkalies are obviously indicated, and it is probable that an increased alkalinity of the blood tends to prevent endocardial irritation, and may soothe an inflammation already present. Until we have some positive knowledge to the contrary alkalies should be freely administered during endocarditis, especially during rheumatic endocarditis. Potassium citrate in 2-gm. (30 grain) doses in wintergreen water, should be given every three to six hours depending on how readily the urine is made alkaline. This may be given with the salicylic acid treatment and also when the salicylic acid has been stopped. It may be well, if sodium salicylate is being used, to give also sodium bicarbonate, the sodium bicarbonate often preventing an irritation of the stomach from the sodium salicylate, the dose being equal parts of the sodium salicylate and the sodium bicarbonate administered in plenty of water. If some other form of salicylic acid is preferred, novaspirin, which is methylene citrylsalicylic acid and contains 62 per cent. of salicylic acid, is perhaps the least irritant to the stomach of the salicylic preparations. This drug is decomposed in the intestine into its component parts, salicylic acid and methylene citric acid. If this drug is combined with sodium bicarbonate the disintegration into its component parts would be likely to occur in the stomach.

It is essential for the welfare of the patient, especially after a long illness before the complication of endocarditis could occur, and in rheumatic fever in which all meat and meat extractives have been kept from the diet, that small doses of iron should be administered daily. Not only the fever process but the salicylic acid tend to prevent the healthy normal growth of red corpuscles, and such patients suffering from rheumatism are often seriously anemic after the acute inflammation has ceased. The iron administered may be 5 drops of the tincture of the chlorid in lemonade or orangeade, twice in twenty-four hours (and it should be remembered that lemon and orange burn to alkalies in the system and do not act as acids), or 0.1 gm. ($1\frac{1}{2}$ grains) of reduced iron in capsule twice in twenty-four hours, or a 5-grain tablet of *Eisenzucker* (saccharated oxid of iron) twice in twenty-four hours.

As so many times repeated, real pain must be stopped, and morphin either by the mouth or hypodermatically should be used to the point of stopping such pain. If the patient is a young child, the sulphate of codein or the deodorized tincture of opium may be used in the dose found sufficient, and either one will act satisfactorily. The dose given should be small and repeated sufficiently often to stop the pain. The dose necessary for the given individual will soon be learned, and that dose may be repeated at such intervals as the condition may require. Sometimes the hypnotic selected, if one is needed, will be sufficient to quiet the cardiac aches or pains.

If there is much restlessness and the circulation is good, that is, if myocarditis is probably not present, the bromids may be of great value, especially in children. The dose should be sufficient to quiet the nervous system. The drug may be discontinued after a few days if the conditions improve. If the bromid, except in large doses, will not cause sleep, a sufficient dose of chloral should be given. Chloral is one of the most satisfactorily acting drugs to produce sleep and to cause cardiac rest that we have. While it should not be given if there is real cardiac weakness, the good that it does is so much greater than the possible bad effect on the heart that it should not be forgotten for some newer hypnotic. The worst part of this drug is its taste, and the best way to administer it is to have it in solution in water and the dose given on cracked ice with a little lemon juice, to be followed by a good drink of water and a piece of orange pulp for the patient to chew. Ordinarily a bad-tasting drug such as chloral is well administered in effervescing water, but effervescing waters are generally inadvisable when there is any kind of inflammation of the heart, as they are likely to cause distention of the stomach and pressure on the heart. Some physicians prefer chloralamid as a less disagreeable drug and one that acts almost as efficiently as chloral. As the dose of this must be larger than the dose of chloral, it is a question of doubt as to which is the better drug to use. Of the newer hypnotics, veronal-sodium (sodium-diethyl-barbiturate) is among the best. It acts quickly, is less depressant and is a safer salt than most of the other newer hypnotics. It is the readily soluble sodium salt of veronal (diethylbarbituric acid). When combined with any active drug, sodium seems to make it less toxic and less depressant. The dose of this drug is 0.2 to 0.3 gm. (3 to 5 grains).

If the patient is weak, the circulation depressed, the blood pressure low, and the heart rapid, the drug advisable to produce rest and sleep is almost always morphin or some other form of opium. Morphin, with few exceptions, is a cardiac tonic and a cardiac stimulant, unless the dose is much too large. As long as the bowels are daily moved and the food is not given at the time of the full action of the morphin, when digestion might be delayed or interfered with, in most patients the action of this drug during serious illness is entirely for good. The greatest mistake in using morphin for the production of sleep, or for physical and mental rest and comfort when there is not severe pain, is in giving too large a dose. If pain is not severe, or is due to inflammatory distention of some undilatable part, to pressure on some nerve, to distention of some tube by a calculus or to some serious injury to the nerves, large doses of morphin are not needed. Small doses will act much more efficiently. It is excessively rare that a hypodermic of one-fourth grain of morphin sulphate is needed, except for the conditions enumerated. It is often a fact that so small a dose as one-eighth grain of morphin or even one-sixth grain will cause sufficient stimulation of a nervous patient, because its primary stimulant effect on the spinal cord is greater than its depressant effect on the brain, to require another dose (one-fourth grain altogether) to give such a patient rest. On the other hand this patient may many times be quieted by one-tenth grain of morphin sulphate on account of the size of the dose being not sufficient to stimulate the spinal cord. Many a time clinically when one-eighth grain has failed, a dose of one-fourth grain having been apparently necessary, a change to one-tenth grain has proved entirely and perfectly satisfactory, much to the surprise of the attending physicians.

As intimated above in the paragraph on "prevention," the diet during endocarditis must be carefully regulated. It must be sufficient, it must be appropriate for the disease in which the complication occurs, but it must be in such dosage and must be administered with such frequency as to cause the least possible indigestion. Large amounts of milk are rarely advisable. Too much milk is certainly given, even in rheumatism. While pretty well tolerated by children, it is often badly tolerated, as far as digestive symptoms are concerned, by adults. The amount of liquid given should be governed by the amount of urine passed and by the amount of perspiration The patient should not be overloaded with liquid if he does not need it

If the bowels are known to be in excellent condition and not loaded with fecal matters, brisk catharsis is not needed simply because endocarditis has developed If the bowels have been neglected, a small dose of calomel, aided by a compound aloin tablet, is necessary and good treatment Subsequent movements of the bowels should be daily obtained by vegetable laxatives with occasional enemas, as needed With an inflammation of the heart and the possibility of myocarditis developing or being actually present, it is not advisable to use salines freely or often

Whether any drug should be used which acts directly on the heart is often a question for decision As endocarditis is generally secondary to some acute disease, the patient has become weakened already and the circulation is not sturdy, therefore such a drug as aconite is probably never indicated The necessary diminished diet, catharsis, hypnotic, salicylic acid and alkalies all tend to quiet the circulation and diminish any strenuosity of the heart that may be present Unfortunately, during fever processes digitalis in ordinary doses rarely slows the heart, and while it might slow the heart if given in large doses, it would also cause too powerful contractions of the ventricles Digitalis is inadvisable if there is much endocardial inflammation, and especially if there is supposed or presumed to be myocardial inflammation If a patient had already valvular disease from a previous endocarditis, and during this attack insufficiency of the heart was evidenced by pendent edemas, digitalis should be administered but it probably should not be given to other patients during the acute period of inflammation

During rheumatism the peripheral blood-vessels are generally dilated and the skin perspires profusely This is caused not only by the rheumatism, but also by the salicylates The surface of the body should be sponged with cold, lukewarm or hot water, depending on the temperature, especially of the skin The cold water will reduce the temperature and tone the peripheral blood-vessels, the hot water, if the temperature is low and the skin moist and flabby, will cleanse it and also tone the peripheral blood-vessels If the blood-vessels are dilated and the perspiration profuse, atropin is indicated, both as a cardiac stimulant and contractor of the blood-vessels and as a preventer of too profuse sweating The dose should be from 1/200 to 1/100 grain for an adult given two or three times in twenty-four hours, depending on its action and the indications It should be remembered that atropin is not a sleep producer, it may stimulate the cerebrum Therefore at night it might well be combined with a possible necessary hypodermatic injection of morphin

The question of the advisability of strychnin is a constant subject for discussion Strychnin is overused in most patients who are seriously ill In a patient in whom we are trying to cause nervous and muscular rest strychnin is certainly contra-indicated On the other hand if the heart is acting sluggishly, the peripheral circulation is imperfect, and atropin is not acting well it is advisable to give strychnin in a dose not too large and not too frequently repeated Strychnin should be avoided if possible in the evening so that the patient may sleep Whether it should be given by the mouth or hypodermatically would depend entirely on the seriousness of the condition Once in six hours is generally often enough for strychnin to be administered unless the dose is very small

It is rarely, if ever, advisable to use alcohol In certain instances however especially in older patients who are accustomed to alcohol, a little whisky administered several times a day may act only for good, both as a food and as a peripheral dilator But it must be remembered that alcohol is not a cardiac stimulant, and that a large dose will be followed by more cardiac depression Nitroglycerin may act as well as whisky in the kind of cases mentioned Caffein stimulation in any form is generally inadvisable during inflammation of the heart

The duration of acute endocarditis varies greatly, it may be two or three weeks, or the inflammation may become subacute and last for several months Although mild endocarditis rarely causes death of itself it may develop into an ulcerative endocarditis and of course then be serious *per se* On the other hand it may add its last quota of disability to a patient already seriously ill and death may occur from the combination of disturbances

As soon as all acute symptoms have ceased, rheumatic or otherwise, and the temperature is normal, the amount of food should be increased the strongly acting drugs should be stopped, especially the alkalies should not be given too long, and the salicylates should only be given intermittently if at all, iron should be continued, massage should be started and iodid should be administered, best in the form of the sodium iodid, 0 1 to 0 2 gm (1½ to 3 grains), twice in twenty-four hours, with the belief that it does some good toward promoting the resorption of the endocardial inflammatory products and can never do any harm Prolonged bed rest must be continued, visitors must still be proscribed long conversations must not be allowed, and the return to active mental and physical life must be most deliberate

No clinician could state the extent to which the valvular inflammation will improve or how much disability of the valves must be permanent It is even stated by some clinicians that a rest in bed for three months is advisable While this is of course excessive, certainly when the future health and ability of the patient are under consideration, and especially when the patient is a child or an adolescent, time is no object compared with the future welfare of the individual s heart It is one of the greatest pleasures of the clinician to note such a previously inflamed heart gradually diminish in size and the murmurs at the valves affected gradually disappear Although they may have disappeared while the patient is in bed he is not safe from the occurrence of a valvular lesion for several months after he is up and about

While the discussion of hygiene would naturally be confined to the hygiene of the disease of which the endocarditis is a complication, still the hygiene of its most frequent cause rheumatism should be referred to Fresh air and plenty of it and dry air if possible is what is needed in rheumatism and a shut-up overheated and especially a damp room will continue rheumatism indefinitely It is almost as serious for rheumatism as it is for pneumonia Sunlight and the action of the sun s rays in a rheumatic patient s bedroom are essential if possibly obtainable

As so many rheumatic germs are absorbed from diseased or inflamed tonsils or from other parts of the mouth and throat proper gargling or swabbing of the mouth and throat should be continued as much as possible even during an endocarditis

SATURDAY NOVEMBER 23 1912

SOCIALIZING THE BRITISH MEDICAL PROFESSION

As our readers are aware if they have followed our London letter from week to week, a bitter conflict has been going on in Great Britain over the terms of the so called Insurance Act. It is a peculiar fact that although this law is probably the most revolutionary, so far as medical practice is concerned of any measure yet introduced in any English-speaking country, the controversy between the government and the physicians has been almost entirely over the question of compensation and not over the principles on which the law is based. And yet if we are not mistaken, this law marks the beginning of the end of the old system of the individual practice of medicine and of the old relationship between patient and physician — the beginning of a new era, both for society and for physicians. It provides for nothing less than an assumption on the part of the government of the responsibility of providing proper medical care for citizens who are financially unable to secure it for themselves. Under the terms of the act all persons whose total annual income is less than $800 (£160) will be entitled to medical services furnished by the government and paid from a fund made up jointly by workmen employers and the government. Persons having an income above $800 will continue to provide their own medical services as heretofore — for the present. It is estimated that approximately 15 000 000 of the inhabitants of the United Kingdom are by the terms of this act taken out of the field of private practice.

The effect of such a law can be nothing less than revolutionary as far as the economic conditions of the medical profession are concerned. That the discussion has centered almost entirely around the question of compensation shows that physicians have no objection to being made state health officers or to having the present system of private practice largely reduced, if not abolished so long as they are adequately compensated for their work. Another significant fact showing both the disregard of the medical profession by the average politician and the evident lack of understanding [illegible] the medical profession and the public is that in urging the bill the Chancellor of the Exchequer [illegible] of any effort to find out what provisions would be satisfactory to physicians themselves although the burden of the new system would fall entirely on the physicians. The British Parliament passed the bill at the personal insistence of Mr Lloyd George, in spite of the opposition of the British Medical Association which protested among other things that the compensation contemplated was inadequate. Following the passage of the bill the majority of the profession in Great Britain refused to work under the law in its present form and have demanded an increased compensation, as well as the modification of some other features.

The question of a fair and adequate compensation for physicians is, of course, vital. It is, however, largely a local question since a standard of compensation which might be perfectly suitable to one country, or to one locality, would not necessarily be fair to another. Physicians in the United States will, therefore, be more interested in the general plan of the measure. The amount of compensation and the fixing of a maximum income for those coming within the provisions of the law are incidental questions. The important feature is the recognition of the fact that it is the duty of society, as represented by the government, to furnish medical treatment for those who are unable to secure it for themselves. It also means the recognition of the modern physician as a health officer of the state, working for the general good, rather than as a private, professional or business man.

There is room for much speculation as to the ultimate results. For one thing, it practically eliminates the necessity for medical charity and so stops the enormous drain on physicians which has resulted therefrom. If it is true, as was reported several years ago by a committee of one of our large local organizations, that 25 per cent of the professional work done by physicians is entirely gratuitous, the abolition of this enormous nonproductive class of work would be beneficial. Another important consideration is that the adoption of such a plan would do away with any possible mercenary motive which might be alleged against the individual physician or the medical profession as a whole, as a reason for any indifference or apathy toward the development of preventive medicine. A third and by no means less important result will be that those persons who, under the present private practice system are the least able to consult physicians frequently, and who are yet most exposed to and susceptible to preventable diseases can secure the advice and services of medical men before rather than after the disease has developed. That some form of periodic, systematic medical inspection will develop out of the state system of medicine thus created in the United Kingdom seems probable.

Last is the effect which such a measure will have on medical education and the personnel of the profession. If the state assumes the responsibility of providing medical services for any large proportion of its citizens, it must necessarily pay strict attention to the quality of service which it provides, as a physician working under the Insurance Act will be necessarily a representative of the state. This will make it necessary for the government not only to exercise more rigid supervision over medical colleges and the character of medical instruction, but also to adopt some system which will prevent those already qualified to practice from becoming inefficient through laziness or indifference. This necessity has already been recognized in several branches of our own government. For instance, in our Army and Navy, all officers not only are required to pass rigid examinations at the time of their appointment, but are also required to pass examinations at stated intervals, for service and promotion, on pain of compulsory resignation from the service if they fail to qualify. Such a plan compels these officers to keep up with progress in the practical and technical work of their profession.

Physicians in the United States will be interested in the development of this plan in Great Britain principally on account of the light it will throw on such a plan in this country, for the possibility that the adoption of some arrangement of this sort will sooner or later be considered on this side of the Atlantic may be acknowledged. The prevention of disease is becoming more and more recognized as a social and not a professional duty. Most preventable diseases to-day are due to sins of the community rather than to sins of the individual. The state in the future must protect the citizen against disease just as it now protects him from foreign invasion. In fact, the majority of our most dreaded diseases are foreign invaders, as far as civilized nations are concerned.

The lesson which American physicians can learn from the experience of their British brethren is the importance of educating the public on health matters, and of a close understanding and sympathy between the public and physicians. If the relations between the British medical profession and the British public had been as intimate as those which fortunately are now coming into existence between physicians and the people in this country, it would have been impossible for the government to introduce or champion a bill placing such a burden on the medical profession without providing compensation which was fair and adequate. Physicians in all lands and in all times have been generous beyond all other classes in charitable deeds. Yet the physician to-day, as never before, must live comfortably and must have money to pay for instruments, books, journals and graduate instruction, if he is to be able to give his patients such services as they need and as the times demand. The physician of the future, as the official guardian of the public health, must be assured a compensation which will enable him to do his work so that the lives of the people may be protected. If the people understand the importance and value of proper medical services there will be no difficulty about securing fair compensation.

THE PANCREAS AND DIABETES IN THE LIGHT OF NEW EXPERIMENTS

Despite the numerous attempts which have been made from time to time to unravel the secret of the mechanism of diabetes, and despite the failure of any of the proposed theories to afford a convincing solution of the difficulty, the problem retains a perennial interest. For the clinician there is involved the possibility of discovering a therapeutic procedure which would be of the utmost importance for the welfare or rescue of an increasing number of patients, while the physiologist confidently expects to find in the unraveling of the etiology of diabetes, clear indications of the way in which the foodstuffs and notably the carbohydrates are converted into their normal end-products in the organism.

In a previous editorial,[1] reference was made to the possible relation of the liver to certain types of glycosuria. The undoubted involvement of the pancreas in relation to some forms of diabetes at least may be assumed to be familiar. The classic studies on the removal and the transplantation of that organ make it more than probable that the action of the pancreas is exerted through the circulation rather than by intermediation of the nervous system. Presumably there is a chemical factor concerned. The most simple and direct hypothesis assumes that there is produced in the gland some substance — or a hormone, in terms of the recent physiology — which is necessary for the assimilation or utilization of sugar by the tissues. Although the inability to use or oxidize carbohydrate is the conspicuous feature of the diabetes, it is further noteworthy that the utilization of other food derivatives may also be greatly impaired. Amino-acids are said to be excreted in some cases, and the final fatal outcome is commonly characterized by an accumulation of oxybutyric acid and its companions — products associated with the defective catabolism of fats.

There are, however, other plausible hypotheses regarding the pathologic defect underlying the diabetic insufficiency. It has been asserted that the primary difficulty is an increased formation and distribution of sugar in the liver, this organ having become freed from an inhibitory influence previously exerted on it by an assumed internal secretion of the pancreas. Here it is overproduction or failure to conserve carbohydrate properly rather than inability of the tissues of the body to utilize sugar which is made to account for the phenomena. Again it has been suggested that the pancreas ordinarily furnishes some antidiabetic product, acting like an antitoxin to prevent the accumulation in the organism of products which would otherwise injure the sugar-assimilating functions of the cells. The theory of the antitoxic action of internal secretion has been a favorite one in certain quarters and has often been called on to explain the function of the ductless glands. In addition to all the [illegible] sugg[illegible] that the action of the pancreas is not a direct one, but involves the interaction of other organs, such as the thyroid and suprarenal glands.

---

[1] Drugs, Diabetes and the [illegible] 19, 191[illegible], p 1400

There is every reason to believe that the muscles are *par excellence* the tissues in which the ultimate consumption of sugar in the body takes place. The conspicuous energy-changes leading to mechanical work occur in the muscles, and because of their predominant bulk and physiologic activity they stand foremost as the organs of metabolism. Much would be gained, therefore, if it could be demonstrated that there is a difference between the muscles of the normal and of the diabetic individual in respect to the capacity to consume sugar. Knowlton and Starling[2] have devised a method for maintaining the heart and lungs of a mammal for many hours in a state approximating normal, while these organs are artificially fed with blood. This has made it possible to compare the performance of heart muscle from various subjects in relation to the character of the blood supplied and the inherent properties of the tissues themselves. Diabetes was produced in animals by removal of the pancreas, and the hearts of such individuals were employed for comparison with the hearts of healthy subjects. The heart muscle of dogs, fed with normal blood, consumes about 4 mg. of glucose per gram of heart per hour. This power of consuming sugar is reduced to a minimum or disappears altogether in hearts taken from animals which have undergone complete excision of the pancreas. The addition of a boiled extract of the pancreas to the blood circulating through the heart of a diabetic animal restores to the latter the power of utilizing the glucose of the circulating blood. From such facts the impression is gained that the pancreas normally produces a substance which is continually discharged into the circulating blood — a pancreatic hormone — the presence of which is a necessary condition for the assimilation of circulating glucose. Removal of the pancreas brings about the disappearance of the substance from the blood and therefore deprives the tissues of the possibility of utilizing carbohydrates as sources of energy. Knowlton and Starling frankly admit that other explanations are not absolutely excluded, however plausible the above deduction may appear. The well known earlier contributions of Professor Starling's laboratory, which have led to the newer conception of hormones in general, inspire confidence in the tentative hypothesis suggested by the perfusion of the isolated heart and assure it a respectful hearing.

THE RESUSCITATION OF THE HEART

More than a quarter of a century ago the physiologist Schiff demonstrated on animals the possibility of resuscitating the apparently dead by means of massage of the heart. Enough experience has been gathered in the meantime to encourage the continuance of this method in appropriate cases. Our knowledge of the working of the heart — its innervation, the coordination of its parts, the intrinsic and extrinsic factors on which a normal cardiac functioning depends — have been so widely extended in the past few years that there is hope of the continued fruitful application of these newer acquirements in the domain of medical practice.

Even under what appear to be most favorable conditions, massage often fails to make the heart beat. Irritability and the power of contraction may be maintained in the organ, but the inner stimulus may be lacking and spontaneous rhythmicity fail to develop. Professor Joseph Erlanger of the Washington University Medical School in St. Louis, to whom science owes numerous valuable contributions in the domain of cardiac physiology, has offered some promising suggestions bearing on the resuscitation of the heart.[1] Contraction of the ventricles can frequently be induced by the more familiar methods. Direct electric stimulation of the ventricles is fraught with considerable danger, since it is extremely liable to set up fibrillation. In attempting to initiate the rhythm of the heart in some other way, Erlanger has proposed to supply, if possible, the impulses along the usual path by which the auricles are normally started beating. The function of the sinus region as a cardiac pace-maker is now well known. Experiments on isolated heart preparations have shown that whereas stimulation of other parts of the auricle rarely if ever results in the development of a series of beats, short periods of tetanic stimulation of the sinus region materially increase the carrying power, into the less rhythmic regions of the auricle, of the impulses originating in the sinus. In this way previously quiescent outlying regions may begin to respond to sinus impulses, or a feebly beating outlying region may begin to beat more strongly.

Since it has been demonstrated on the freely exposed heart that stimulation of the sinus region is a valuable adjunct to massage in the resuscitation of the heart, Erlanger succeeded in applying this principle without formidable surgical procedure such as the extensive opening of the chest requires. A sound carrying a stimulating electrode can be inserted through a small costal interspace opening so that its point will reach the sinus region of the heart exactly, without encountering any resistance whatever. Unipolar stimulation of the sinus can then be employed as an adjuvant to subphrenic cardiac massage. The method has been successfully applied to animals apparently dead from the effects of chloroform in the usual way. Artificial respiration by the insufflation method of Meltzer and Auer is quickly started, the stimulating sound inserted, and the massage given through an incision in the abdomen. The value of the procedure as an accessory in permanent resuscitation has been demonstrated in enough trials on dogs to indicate its feasibility in man. The accidents due to experimental manipulation were few, though there are obvious sources of danger, such as puncture of the heart or lungs, but the respiratory center may fail to recover even when the cardiac performance becomes satisfactory.

[2] Knowlton, F. P., and Starling, E. H.: Experiments on the Consumption of Sugar in the Normal and Diabetic Heart, Jour. Physiol., 1912, xlv, 146. The method is more fully described in the Journal of Physiology, 1912, xliv, 206.

[1] Erlanger, J.: Sinus Stimulation as a Factor in the Resuscitation of the Heart, Jour. Exper. Med., 1912, xvi, 452.

The results thus achieved experimentally will doubtless encourage others to apply this method of resuscitation to man when a favorable opportunity arises. The occasional death from an overdose of chloroform on the operating-table furnishes an illustration of the possibilities always liable to arise. Animal experimentation in the hands of competent workers has contributed another example of its beneficent aims and its potent helpfulness.

THE ENTRANCE AND EXIT OF SUBSTANCES INSOLUBLE IN WATER IN THE ORGANISM

The mode in which the organism eliminates water-soluble substances that are not burned up in the nutritive processes is familiar. They leave the body through the kidneys and are discharged in the urine, unless perchance the path of excretion is into the intestine, when they pass out with the feces. In the latter way iron, calcium and magnesium, for instance, may become eliminated. Familiar drugs and poisons likewise take one of these channels, the kidneys acting *par excellence* as the excretory organs. Only in the case of volatile substances are the lungs called into play for this function.

It happens occasionally that compounds which have only a sparing solubility in water reach the circulation. How they penetrate the alimentary wall has been somewhat of a puzzle. A few years ago, when it was still supposed that fats were absorbed as such in emulsion, and that they traversed the intestinal mucosa in the form of minute globules which reappeared in the lymph-stream of the lacteals beyond the absorbing membrane, it was not difficult to explain the similar translocation of other particles which are insoluble in the intestinal contents. To-day, however, it is almost universally taught that fats are not only emulsified but actually hydrolyzed in the digestive processes, so that it is not neutral fats, but rather the products of the lipolytic change—glycerol, soaps and fatty acids—which find their way into the absorbing mucosa. Digestion, that is, hydrolytic cleavage, is accordingly just as fundamental a prerequisite for the utilization of fat as it is for the absorption and assimilation of the other groups of nutrients. In line with this is the evidence that unsaponifiable — that is, indigestible — substances like mineral oils or petrolatum fail to enter the circulation and that they pass through the alimentary tract unchanged, as a rule at any rate. This fact forms the basis for the use of petrolatum by some clinicians in the relief of constipation. The soft unabsorbable residue furnishes a suitable texture to the alimentary contents and a bulk which is conducive to spontaneous evacuations. Conversely, the emulsified fat, once it has reached the blood, rarely finds its way out through the walls of the kidney tubules except in most unusual circumstances leading to lipuria. The secretory and absorption membranes are as a rule impervious to suspensions such as the fat globules represent.

There are substances which lack the property of solubility in water but are soluble in fats and oils. The chlorophyl of the green vegetables and the coloring-matter of butter and egg-yolk are familiar illustrations, while a number of common drugs might be cited as additional examples. Do they ever leave the lumen of the bowel in their transit along the digestive tube, or are they always lost with the feces? Recent investigations on the behavior of fat-soluble dyes are likely to throw a new light on this question.[1] Scarlet-red, which has lately received notice as a therapeutic agent,[2] Sudan III, indophenol and annatto are types of these stains which are insoluble in water, soluble in fats and comparatively harmless. Some of the dyes of this class have long been in use for coloring certain food materials artificially. When they are introduced into the organism by various paths they are deposited in the adipose tissue and bone-marrow, which is rich in fatty materials. In investigating the mode of entry and exit of these substances, Mendel and Daniels have found that all are strikingly soluble in bile or solutions of the bile salts. When they reach the intestine, therefore, they can enter the portal circulation dissolved in reabsorbed bile or can find their way into the organism in company with the fat or its derivative fatty acid. They do not pass beyond the liver in the one case, or the lacteals in the other, unless fat is present to transport them, for they cannot travel in solution in the fat-free blood plasma. These dyes follow the fat to the liver under conditions in which such migration takes place either from the fat depots or the circulation itself. In the hepatic cells, however, the dye is separated from the fat and secreted along with the bile into the intestine. From here it may be reabsorbed as before and a cycle of travel established until after gradual losses the last of the pigmentary substance escapes with biliary residues in the stools.

The significance of these findings is more far reaching than a hasty consideration may disclose. They show the bile in the important rôle of a solvent for substances which are insoluble in ordinary watery vehicles or even in blood, and by virtue of this property such compounds may be carried both into and out of the circulation. If they find a suitable carrier like fat they continue to travel *in the body along with this constituent, but in* its absence they are forced to make their exit again along with newly secreted bile. The phenomenon is one which doubtless applies to all compounds not transformed in the body which are more soluble in bile than in water or serum. It is well known that the bile forms the normal channel of elimination of numerous substances and it is reasonable to assume that such substances belong to the solubility category just outlined One may stop to speculate on the possible therapeutic properties of a compound which can thus be made to traverse the paths of the biliary secretion which are occasionally the routes of bacterial invasion

[1] Mendel, Lafayette B., and Daniels, A[illegible] [illegible] Behavior of Fat-Soluble Dyes and Stained Fat in the A[illegible] [illegible] Jour. Biol. Chem., 1912, xiii, 71.

[2] [illegible]

When the fat-soluble dyes (and presumably this is true for comparable drugs) are transported in the organism with an abundance of food-fat they may find their way into the mammary secretion, according to the observations of Mendel and Daniels One can thus understand how the color of the milk-fat may be influenced by the content of lipochromes in the food, and the facts of daily experience receive a logical explanation The Yale investigators have never found dye in the fetus or newly born young when the mothers were fed on stained food The failure to traverse the placenta emphasizes anew the barrier which this membrane offers to the passage of substances through it and recalls the much-debated question of the real origin of fetal fat

THE CLINICAL MANIFESTATIONS OF EPIDEMIC SORE THROAT

There is a pronounced resemblance in the symptoms and clinical course of the various milk epidemics of sore throat to which attention has been directed of late This is shown clearly in the reports of the Christiania, Boston and Chicago[1] outbreaks In all three the disease is described as beginning suddenly, with or without chill, followed by fever, muscular pain, headache, sometimes nausea and vomiting, prostration, and the usual local symptoms of a more or less severe follicular and membranous tonsillitis and pharyngitis In the Chicago epidemic the pulse seemed relatively slow, and Brooks[2] also notes that in the outbreak described by him the pulse-rate was not increased in proportion to the fever Naturally diphtheria was first suspected and in Christiania the notice of the health department was aroused by the large number of throat cultures sent in by physicians and found to consist of streptococci only Usually the lymph-nodes in the neck became enlarged, sometimes very much so, but in some cases they were tender without marked swelling A moderate leukocytosis has been noted

In most cases of the recent epidemics the attack would subside rather abruptly after a few days, the patient remaining prostrated, however, and regaining strength only slowly, but not infrequently a second attack with even severer symptoms than the first would set in after a week or so of improvement This tendency to relapse has been noted in the earlier epidemics also

The great danger in epidemic sore throat lies in extension and generalization of the infection, and it is this tendency which stamps the disease as peculiar and as due to a virus of special virulence In the recent epidemics, besides abscesses in the neck, often deep-seated, there were encountered otitis, glossitis and other local complications, erysipelas, purpuric and scarlatiniform eruptions, acute articular rheumatism or conditions indistinguishable therefrom with or without endocarditis, and also suppurative arthritis, pneumonia, peritonitis and other septicopyemic manifestations Instances of phlegmonous angina have been described Davis[3] observed that when there was pronounced glandular involvement of the neck, cultures of the blood were usually sterile, while in many cases with no special enlargement of the glands, streptococci would be obtained, and in such cases visceral lesions were common In the Boston epidemic[4] the gravity of the complications seemed most serious in persons between the ages of 40 and 60 "Cambridge is like a city of the plague Whomever one meets the talk is all of who is ill, who has had a relapse, who has died" In children there seemed to be a degree of relative immunity, and when the infection took hold in children the symptoms were gastro-intestinal in nature (Darling)

Statistics giving the relations of the various outstanding manifestations of general infection to the different age periods are not available, nor is anything reliable known in regard to the death-rate That it may be high, higher perhaps than at first expected, would seem to be indicated by the observations of Capps and Miller on a group of 173 cases in which nineteen deaths occurred, it is probable, however, that these were all exceptionally severe cases It is of interest that of the nineteen that died nine had peritonitis, in other epidemics also peritonitis is mentioned as present in about half of the fatal cases

Preble,[5] in commenting on the peculiarities of the clinical picture of the Chicago cases, states that a temperature of 102 might be associated with a pulse of 40, and one of 104 or 105 with a pulse between 80 and 90 He noted also that even in prolonged cases, extending over months, there would be little anemia, and that jaundice was rare, all of which leads him to suggest that possibly it concerned infection of some other type than with the ordinary streptococcus

In order to secure a more accurate knowledge of the nature of the disease in question, there is need now of careful and systematic study on a comprehensive scale of many individual cases during their entire course Unquestionably a great deal of interest and practical value would be brought to light if studies of this kind could be undertaken from the very onset of epidemics, and for this reason as well as in the interest of prompt prevention of further spread, special efforts should be made to recognize outbreaks in the earliest stages Only in this way can we learn whether we are dealing with more than one disease, whether milk may convey still unknown diseases which like scarlet fever and small-pox open the door to streptococci, or that it concerns, as is now taken for granted, only the varying manifestations of primary streptococcus infection.

"FROM THE EAST, LIGHT"—AND DISEASE AND DEATH

Ex oriente lux has long been an adage emphasized by those whose education or habits of thought were more or less derived from Eastern sources. That the sun's lighting comes from the East is an accident of the earth's direction of rotation, and that from the Orient first came the semicivilized races to start a better civilization in the Occidental world is also due to another "accident"— that of climate, which allowed man to rise out of savagery. The half-way house, as it were, of the migrating Oriental was the Mediterranean semicivilization, which bore within its blood the germs of its own death, and which was illustrated in the fall of the Roman Empire.

The heart of orientalism is belief in the supremacy of fate, which cannot be withstood or surmounted. This implies slavery to disease and death. The Oriental supinely accepts disease, even when plainly due to his own sin or recklessness or when easily obviable or curable, as the unalterable law of fate, either as punishment for spiritual sin or as the vindictiveness and tyranny of his irresponsible and unseen rulers. A contradictory attitude characterizes the Occidental point of view. Disease and premature death are not the result of fate, but may be prevented or cured. The history of medicine and of diseases everywhere demonstrates this truth. The best illustration is the marvelous statistical record of suddenly occidentalized Japan in her late war as regards the death-rate of her soldiers.

Compare that with the reports which come as we write of the Turkish conditions in Constantinople. This city of over a million inhabitants, in constant touch with our Western civilization, is sewerless and so insanitary that the banished "street scavengers," the dogs, would have partly prevented the present unspeakable accumulations of filth "even in the most important thoroughfares." Cholera, Asiatic cholera, small pox and typhus are reported to be raging and Occidental Europe, despite all its hygiene and medicine, may soon be overswept by these dread diseases.

The lesson to be learned, treasured and put into action, is that for self-protection, if not for a better motive, scientific medicine should be organized and should extend its power — its gospel — to these laggards in civilization in Oriental countries. Hygiene and preventive medicine are their greatest need, to give it to them our greatest privilege and duty. The medical missionaries have done much to break the news to the Oriental, but they have had so little power and their number has been so few that their work has been largely individual and curative rather than social and hygienic. Here is a sadly neglected opportunity for the thousands of philanthropic capitalists of our Occidental nations to lift the Oriental world out of its disease-scourged and death-bitten fatalism. We in the West have the right to demand in self-defense, if for no other reason, that the greatest evils of life shall not be loaded on us by the inefficiency and laziness of a nerveless fatalism. The medical profession is prepared and able to second such a hygienic crusade.

Current Comment

SUGGESTION AND SUICIDE

That the suggestive effect of reading details of suicides is a powerful factor in the causation of suicide among susceptible persons is recognized. The suggestion is more likely to have influence when in the account of the suicide some poisonous article commonly found in households, such as phenol, Lysol and Rough on Rats, is named as the agent employed by the suicide. In New South Wales newspapers have been asked by the pharmaceutical board not to publish the names of poisons used by suicides. In several instances leading newspapers have heeded this request, particularly in connection with Lysol poisoning cases, which are numerous in all the states of the commonwealth.[1] The House of Delegates of the American Medical Association in 1910, adopted resolutions[2] to the effect that the publication of details of suicides in newspapers is one of the potent causes of other suicides through suggestion, and it was recommended to the public press that the details of suicides be omitted from publication. In an editorial[3] referring to this action of the House of Delegates we made certain recommendations by which the influence of the publication of details of crime might be tested. While it is the consensus of opinion that the publication of details of suicides does promote further similar acts, the newspapers assert that it is their duty to publish the news. In adopting this attitude the newspapers are assuming a serious responsibility, and some authoritative restriction of such publication would seem to be desirable. A definite and strong expression of public opinion against this practice would no doubt have a better effect even than legal enactment.

THE DEATH OF THE HEART

Many a physician will recall the lesson in elementary physiology which introduced him to what Huxley fancifully called the "tripod of life"—the brain, lungs and heart. The heart is the last leg on which life ultimately stands, and it becomes a matter of no little interest to know how the most vital of organs enters the state known as death. What is the last part to die? The stimulus of the heart beat apparently originates in the region at the junction of the superior vena cava with the right auricle Here rhythmicity is most highly developed and here it has been assumed that life takes its last stand at the spot where the cardiac pace-maker is located In the hospital of the Rockefeller Institute for Medical Research at New York, Dr G Canby Robinson[1] has made records from patients before and during the actual stoppage of the heart, using the electrocardiograph, which can be employed without disturbing the individual in any way Cardiac activity in some form or other may persist for more than half an hour after all the usual clinical signs of death have occurred — after respiration has finally ceased, when no heart signs can be heard, and muscular relaxation and the general appearance of the patient indicate that death has ensued There was no uniformity in the changes in the mechanism of the heart-beat Sometimes the ventricular outlasted the auricular activity, in other cases this was reversed, or the two parts of the heart were found to cease synchronously Complete dissociation between the two divisions of the heart, ventricular fibrillation and other disturbances of coordination were among the phenomena noted In view of such an inconstant variety of lethal phenomena Robinson is led to conclude that when death occurs from an acute infectious disease "there is no one point in the human heart which may be considered as the *ultimum moriens*"

A PREMATURE PUFF

The National League for Medical Freedom issues a monthly publication called *Medical Freedom* In its October, 1912, issue, it quotes a somewhat lengthy article from the New York *Telegraph* Part of this article follows

> In view of the restoration to health of Miss Mabel Hite, the actress, it seems to be proper to point out to physicians that if they wish to wage successful war on Christian Science healers, they should accomplish what those earnest men and women do Miss Hite is a popular actress known all over the country, and the theater going public was shocked several months ago when it was announced on the authority of physicians that her days were numbered—she is only 26 years old. She was under the care of doctors They used their knives on her body and dosed her with their drugs "Affliction sore long time she bore, physicians were in vain" They told the public that she would die, and her manager called up the *Morning Telegraph* office and announced that the doctors had given her up It was published broadcast.
>
> Then Miss Hite herself was told that she could not live and at the suggestion of her mother she turned to Christian Science Soon she was able to leave her bed, her weight increased, she went out for rides, and last Saturday attended a baseball game She is on the road to recovery
>
> Now the doctors were mistaken when they announced that she was dying, and Christian Science cured her The public will believe with Miss Hite that the healers of Mrs Eddy's church have made her well They robbed death of its terrors, got her in a calm frame of mind set their wills and hers to work and the young woman began to get well
>
> All this leads us to say that physicians who make mistakes in a matter of life and death should go slow in their criticism and their warfare on healers who really heal

To all of which it is unnecessary to make any detailed reply, as the newspapers report that poor Mabel Hite died of cancer, Oct 22, 1912

[1] Robinson G Canby A Study with the Electrocardiograph of the Mode of Death of the Human Heart, Jour Exper Med 1912 xvi 201.

THE TOXICITY OF THE URINE IN MEASLES AND OTHER INFECTIOUS DISEASES

It has been shown by Pfeiffer[1] that in anaphylactic shock and peptone poisoning the urine becomes extremely toxic Aronson[2] has further demonstrated that in poisoning with Friedberger's anaphylatoxin, so called, and also with poisons made of typhoid bacilli a similar toxicity occurs, and Esch[3] has demonstrated its occurrence in eclampsia On the basis of this work, Aronson and Sommerfeld[4] have studied the toxicity of the urine in measles The observation of von Pirquet that in measles during the exanthem there occurs an indifference to tuberculin in patients who have previously reacted strongly, they would explain as the result of an increased resistance to anaphylactic poisons in this disease They found that during the attack there was a remarkable increase in the toxicity of the urine Guinea-pigs injected intravenously with 2 c c of urine from healthy patients showed no noticeable reactions, but animals injected with urine from measles patients died usually in a few minutes or else became extremely ill, the symptoms resembling those of anaphylactic shock Doses as small as 0 5 cm were found to bring about typical reactions The toxicity of the urine is not parallel to the severity of the illness, to the diazo reaction or to the passing of the exanthem There is no rule as to the duration of the excretion of toxic urine, nor does the toxic action bear any relationship to the specific gravity The toxicity is not lost by boiling or freezing, but the toxic substance is dialyzable On reinjection it was found that a first dose gave no protection, and horse-serum also failed to protect In a study of other infectious diseases it was found that a similar toxicity occurs in serum disease, whereas in scarlet fever no such poisonous urine is excreted Aronson and Sommerfeld believe that whereas in measles the exanthem is an expression of anaphylaxis, in scarlet fever it is the direct result of the action of the causal organism on the skin In typhoid, tuberculosis, diphtheria and pertussis the urine was found to be innocuous These results are of interest and, if corroborated, may prove of importance The demonstration of a relationship between measles, eclampsia, serum disease and poisoning with anaphylatoxins may be of value in determining the nature and etiology of the first two It is also suggested that as an aid in differential diagnosis between measles and scarlet fever, between serum disease and scarlet fever and in other exanthems, this reaction may prove of considerable practical value

THE PHYSICIAN IS RESPONSIBLE

We present this week in the Propaganda for Reform department some facts regarding a widely advertised pseudomedical fraud — Duffy's Malt Whiskey While this preparation is not so widely advertised in medical journals as it was, it still appears in the following

PROGRESS AND REACTION

The influence of the propaganda against medical fakes is repeatedly shown and in no way better than in the changing attitude of publishers toward the admission of advertising matter To the disgrace of the medical profession it must be said that as a class the publishers of lay journals are showing a greater desire to rid their advertising pages of fraudulent medical advertisements than are the publishers of medical journals Hardly a week passes without some evidence of the fact This week we have received a copy of the *Pulaski County Democrat*, a newspaper published at Winamac, Ind By the same mail we also received a copy of a Colorado medical journal—the *Denver Medical Times* The newspaper has an editorial entitled "Advertising Fakes," in which[1] the editor tells why the publishers turned down an advertising contract for the "consumption cure" fraud, "Nature's Creation" The medical journal on the other hand, has an editorial entitled, "The Medical Index Expurgatorius and Independent Journalism," in which the editor boasts of the fact that the proprietary preparations advertised in his journal are not confined to those that have been accepted by the Council on Pharmacy and Chemistry for inclusion in New and Nonofficial Remedies Incidentally he takes the opportunity to attempt to belittle both the Council and the American Medical Association A glance at the advertising pages of the *Denver Medical Times* makes plain why the publishers of that journal are not willing to accept the findings of the Council on Pharmacy and Chemistry Practically the whole of its advertising receipts are derived from the exploitation of proprietaries that either have not been approved by the Council or have at various times been shown to be fraudulent or worthless "Nature's Creation" was examined in the Association's laboratory and found to be essentially a solution of potassium iodid in water and alcohol To sell such a mixture as a cure for consumption is of course a fraud When the *Pulaski County Democrat* was offered an advertising contract for the stuff, the publishers wrote to The Journal for information On receiving the data furnished, they naturally refused to lend their advertising pages to perpetuate the fraud "Papine," when examined in the Association's laboratory was found to be essentially a watery-alcoholic solution of morphin with glycerin It is sold under the claims that it does not "show habit-forming tendencies" and "does not suppress the secretions Such claims for a disguised morphin preparation are just as fraudulent as the claims made for Nature's Creation but the *Denver Medical Times* is perfectly willing to sell its pages to exploit this preparation—and many others that are just as bad—and to blackguard those men whom the American Medical Association has seen fit to appoint to investigate and expose fakes of this kind Though it is typical of over two hundred medical journals published in this country, its importance as a medical journalistic factor would not have warranted its mention but for the coincidence of its arrival in the same mail with the *Pulaski County Democrat* The attitude of the *Pulaski County Democrat* is typical of a large class of conscientious newspapers The attitude of the *Denver Medical Times* is equally typical of a large class of self-styled independent medical journals—and the medical profession is to blame? Will physicians clean up abuses of this sort within the profession on their own initiative or will they wait until an outraged public opinion forces them to do so?

Medical News

CALIFORNIA

Commission to Name Health Director—The Oakland Civil Service Board has decided to throw open the eligibility list for candidates for head of the department of health of the city to practitioners all over the United States and the following committee has been named to act with the civil service board to make the elections Dr W F Snow Sacramento secretary of the State Board of Health, Prof Charles Gillman Hyde head of the Board of Sanitary Engineering in the University of California Dr George W Shaw director of the State Hygienic Laboratory and Drs E N Ewer and H C Thomas Oakland

Medical Board Upheld—Judge Sturtevant in a decision made October 29 held that issuance of permits to medical specialists to practice their so called specialties in California, without regular licenses to practice is contrary to the constitution The question was raised by a mandamus petition made by John L Bohannon to compel the state medical board to issue him a permit to practice as a cancer specialist declaring that he had conformed to all the regulations of the medical practice act by showing that he had practiced his specialty for thirty five years and for fifteen years of that time in the state Judge Sturtevant's decision upholds the action of the medical board

ILLINOIS

Contagious Disease Hospital—It is reported that $65 000 has been raised for the North Shore Contagious Disease Hospital Evanston This leaves $35 000 to be subscribed

One Fifth of Town Ill with Typhoid—The State Board of Health received notice November 11 that sixteen cases of typhoid existed in Hillview Green County a village with a population of eighty Dr J C Westervelt Shelbyville assistant secretary of the state board has been sent to Hillview to make investigations

Personal Dr Clarence F Holmberg Springfield was seriously injured in a runaway accident November 12 and is under treatment in St John's Hospital——Dr J F Blackwelder Litchfield was painfully injured in a runaway accident, November 11 —Dr J M Hoyt Fillmore has been appointed local surgeon of the Clover Leaf System——Dr F M Eckard, Peoria has been elected coroner of Peoria County

Chicago

Larger Appropriation Needed—Health Commissioner Dr George B Young has asked for an appropriation of $880 000 for the Health Department for 1913 an increase of $166 000 over the appropriation of 1912 This appropriation will include the money necessary to aid in the enforcement of the milk, cold storage drinking cup and towel ordinances and will provide also for the required addition to the corps of inspectors

INDIANA

Physicians Equip Surgical Ward—Physicians of Indianapolis have contributed the necessary funds to equip the surgical ward of the new building of St Vincent's Hospital The new institution will have accommodation for five hundred patients

Personal—Dr C B Stemen Fort Wayne who has been ill for three weeks has recovered —Dr J A Edmonds Hebron was seriously burned while assisting in putting out a fire at Hebron November 7 ——Dr John M Cunningham has succeeded Dr Eugene B Mumford as inspector of contagious diseases in the city board of health of Indianapolis

KENTUCKY

Health Department Bulletin The monthly bulletin of the Louisville Health Department has appeared [illegible] the title *Health and Hygiene* In the November issue the bulletin features the hookworm investigation and also gives a number of terse health rules

---

[1] This editorial is reproduced in full in the Propaganda for Reform department this issue

Personal—Dr William A Young, Newport, has been appointed surgeon in chief of the Cincinnati Division of the Chesapeake and Ohio Railroad and Drs Carey E Wamsley, Newport, and S P Garrison, Bellevue, have been appointed assistant surgeons——Dr John W Scott, Lexington, while on his way to New York, was stricken with appendicitis and was operated on in a hospital in Altoona, Pa——Dr J T Crice, assistant superintendent of the Central Kentucky State Hospital, Lakeland, has resigned——Dr Henry G Hartman, Louisville is suffering from septicemia following an injury to the right hand received while cranking his automobile

Trachoma—At the regular bi monthly meeting of the Kentucky State Board of Health held in Louisville, November 14, one of the principal matters discussed was the report of Passed Assistant Surgeon John McMullen, U S P H Service, on trachoma as it exists in the mountains of Eastern Kentucky The investigation included six mountain counties and one adjacent county In all 3,974 persons were examined, 12½ per cent of whom were found to be suffering from trachoma For the purpose of this report, diagnosis was made only in positive cases, the suspicious or possibly incipient cases not being included In Knott County about 18 per cent were affected by the disease, including two out of twelve school children In 400 persons not in schools, 102 cases of trachoma were found In about 1,050 individuals examined in this county, 221, or about 20 per cent, were found to be suffering from trachoma In the schools, the percentage of trachoma varied from 2 to 44 per cent, with a general average of about 18 per cent In Perry County 310 persons were examined 52 of whom, or about 16 per cent, had trachoma In Breathitt County out of 614 persons examined, 12 per cent were found to have trachoma In Lee County, out of 668 pupils examined, 8 per cent were found to have the disease In Clark County in the Blue Grass region, in eleven schools containing 436 children, about 3 per cent were found to have trachoma The cure of existing cases is a problem which will require time and money It was suggested that if possible a clinic, such as is now being held by Dr J A. Stucky in Lexington under the auspices of the W C T U Settlement School at Henderson, Knott County, should be established that accurate records should be kept of the cases, and district nurses sent to follow the patients up, and see that the directions of the physicians are carried out A system of movable or field hospitals should also cover the same territory periodically, in order to see the old patients and also any new patients, just as is now being done in the hookworm dispensary system——The State Board of Health has decided to petition the United States Public Health Service to detail two men and such aids as may be necessary, to establish a series of dispensaries in cooperation with the Rockefeller Sanitary Commission and the State Board In these dispensaries attention should be given to trachoma, tuberculosis, hookworm, pellagra and typhoid fever

LOUISIANA

Sanitary Science at Tulane—Three series of courses in sanitary science were started at Tulane University this session for medical science and engineering students specializing in sanitation The medical graduates of this course expect to become health officers or members of boards of health, the science graduates, experts on sanitary biology, and the engineering, sanitary engineers At Tulane the engineering and sanitary laboratories are on the same campus, and the School of Tropical Medicine has at its service the Charity Hospital clinics In the senior class of the sanitary engineering course, instructions are to be given in water supply, framed structures and reinforced concrete construction by Prof Donald Derickson, formerly of Cornell University, and instruction in laboratory work and in sanitary microbiology will be given by Dr Creighton Wellman and his assistants in the School of Tropical Medicine

MARYLAND

Personal—Dr Jeptha E Pitsnogle, Hagerstown, sustained serious bruises by the caving in of a well, recently——Dr Charles G Hill, alienist of the Mount Hope Hospital, was struck by an automobile, November 12, and seriously injured

New Officers—Washington County Medical Association at Hagerstown, November 15 president, Dr W M Reichard, Fair Play, secretary, Dr W D Campbell, Hagerstown

Baltimore

New Emergency Ward at Hospital—The Baltimore and Ohio Railroad has decided to build an emergency ward at the Maryland University Hospital to cost about $5,000 and be in charge of Dr Page Edmunds

Hospital Fund Grows—The building fund of the South Baltimore Hospital now amounts to $16,000 The trustees have decided not to commence work on the building until $20 000 has been secured

Personal—Dr John C Harris, an old practitioner of Baltimore, was stricken with cerebral hemorrhage October 31——Dr G Milton Linthicum has been appointed assistant surgeon of the Fifth Infantry, N G Md, vice Dr W P Morrill——Dr H W Kennard has been appointed assistant superintendent at the School for the Feeble Minded, Owings Mills

MISSISSIPPI

Vital Statistics Law Obeyed.—Reports from the Mississippi State Board of Health indicate that the vital statistics law, which went into effect November 1, is being conformed to, with very few exceptions, by physicians throughout the state.

Health Day—Health Day was observed in Mississippi November 20 The exercises of the day were carried out by the State Board of Health, with the cooperation of the School Improvement Association and the Mississippi Federation of Women's Clubs

NEW YORK

Small-Pox—The State Health Department has been notified that there are seventeen well developed cases of small pox in Hancock, Delaware County

Child Hygiene Bureau Opens—The Bureau of Child Hygiene of the Buffalo Department of Health was opened October 24, with Dr D V McClure in charge

Personal—Dr C S Albertson has been elected president, Dr James K Stockwell, vice president, and Dr G C Elder, secretary of the medical staff of the Oswego Hospital——Dr and Mrs A J Avery, Northville, celebrated their golden wedding anniversary recently——Dr James H Donnelly has been appointed tuberculosis inspector by the health officer of Buffalo

County Fair Health Exhibits—The Bulletin of the State Department of Health for October describes the health exhibit which was exhibited by the department at a series of county fairs, acting in cooperation with the New York State College of Agriculture at Cornell University A special circular entitled "Health Hints for Country Households," was distributed at the fairs, at Batavia 1,750 of these were put in farmers' wagons Prof H N Ogden of Cornell University and of the division of publicity and education of the department was in charge at the county fairs and was called on to answer many questions regarding ventilation, diphtheria antitoxin and adenoids Antagonism to vaccination was frequently voiced and showed the need of educational effort in this direction It is estimated that the exhibit has been visited by not less than 30,000 people

New York City

Cancer Research Fund for Columbia—Executors of the estate of George Crocker have filed their final accounting with the courts which shows that Columbia University has received from the estate $1,563,000 for the cancer research fund

Reception to Dr Carrel—A reception was given in honor of Dr Alexis Carrel of the Rockefeller Institute of Medical Research at the New York University, November 16, when the French ambassador delivered to Dr Carrel the Nobel prize in medicine for 1912

University Club Entertains Surgeons—The University Club, Brooklyn, gave a dinner November 9 at which 300 were present, and among the guests of honor were Mr W Arbuthnot Lane, London, England, and Drs William J Mayo, Rochester, Minn, John B Murphy and Albert J Ochsner, Chicago, Robert C Coffey, Portland, Ore, George W Crile, Cleveland, and Edward Martin and John Clark, Philadelphia

Public Clinics—The Department of Public Charities of the city of New York has issued orders which were communicated to the Academy of Medicine on November 7, that on and after the first of October, 1912, all clinics held in the amphitheater and operating rooms of the hospitals of the Department of Public Charities shall be open to duly licensed graduates in medicine and to students in all regular organized medical schools and colleges It was also ordered that tickets should be issued by the secretary of the Department of Public Charities for distribution by the secretaries of the several medical schools and societies of the City of Greater New York, which would entitle the registered holders thereof to admission to these clinics

OHIO

New Officers—Second District Medical Society at Dayton, October 24 Dr W H Humphrey, Yellow Springs, president

——Tenth District Medical Association at Mount Gilead, October 15 president, Dr J H. Jackson, Edison, secretary treasurer, Dr J J Coons, Columbus The next meeting will be held in Columbus ——Seventh District Medical Association at Coshocton, November 7 president, Dr E B Shanley, secretary, Dr E D Moore, both of New Philadelphia

Hospital News—The entire building fund of $325,000 and $80,000 of the endowment fund have been raised for the new proposed Babies' Hospital, Columbus ——Dominican Sisters have opened a free dispensary in Columbus for the sick poor in cooperation with the local society of St Vincent de Paul ——Creditors of the Eddy Road Hospital, Cleveland, are said to have filed a bankruptcy petition in the federal court and asked for a receiver ——The name of the Women and Children's Free Medical and Surgical Dispensary, Cleveland, has been changed to the Woman's Hospital of Cleveland

Personal.—Dr W M. Bucher, Cleveland, has been appointed superintendent and resident physician of the Municipal Tuberculosis Sanatorium at Warrensville ——Dr G W Garrison, Utica, is reported to be seriously ill as the result of a cerebral hemorrhage ——Dr William T Miller, Cleveland, has been reappointed a member of the State Board of Health ——Dr James McKinley, Harrisburg, is reported to be seriously ill with nephritis

PENNSYLVANIA

The Cost of Small-Pox.—Pittsburgh expended $42,024 91 in its recent efforts to avert an epidemic of small pox.——The expense of the recent small pox epidemic to Carbondale as estimated by the State Department of Health is $31 000

Contagious Diseases—In spite of the efforts to check the spread of diphtheria in Allentown, eight new cases were reported on November 11, making a total of 125 Dr C J Hunt, associate chief medical inspector, found that cases were not properly followed up by health officers and all cases were not isolated. The reports of the health department, Harrisburg, show 11 cases of the disease reported in August, 30 in September, 95 in October and 24 so far this month ——Pittsburgh has succeeded in stamping out epidemics of small pox and diphtheria, only to be followed by one of measles, 1,500 cases of that malady having been reported to the department of health of Allegheny County up to November 14

Personal.—Dr D E Sable, police surgeon of Pittsburgh, is under treatment at the South Side Hospital for a nervous breakdown ——Dr Guy A Gerberich, Lebanon, who has been seriously ill with typhoid, is reported to be improving.——Dr W H. Robinson Pottsville is reported to be seriously ill ——Dr George R Reich and family, Marietta, have returned after a stay of several months in Bassano Canada ——Dr George W Seibert, Lebanon, who spent the summer recuperating in the Mound Valley region, has returned and resumed practice.——Dr J M Maurer, Shamokin, who has been seriously ill, is reported to be improved ——Dr Ulysses E Dornsife is reported to be ill at his home in Tunkhannock ——Dr George Romig Allentown, fractured his arm while cranking his automobile, October 28

Philadelphia

Physicians' Home Urged—At the meeting of the members of the Aid Association of the Philadelphia County Medical Society, November 11 Dr Roland G Curtin urged that steps be taken to establish a home in Philadelphia for aged and destitute physicians and their wives

Portraits Presented to the College of Physicians—At the meeting of the College of Physicians November 6 portraits of the late John H Musser Isaac Hays and Wharton Sinkler were presented to the college by Drs George A Piersol George I DeSchweinitz and James C Wilson, respectively

To Collect Criminal Statistics—The collection of statistics relating to crime in Pennsylvania is to be undertaken by the state branch of the American Institute of Criminal Law and Criminality The committee selected to prepare this report consisted of Edward Lindsey, John Lisle and Prof William I Mickle of the University of Pennsylvania

New Dispensary for Tuberculosis Opened.—The free dispensary system, being built up by the state in its fight against tuberculosis opened a new branch at 1120 South Twenty Sixth Street, for the benefit of the Woodland and Darby sections of the city This is the third branch now operating in this city and the one hundred and sixteenth to be established in the state Dr S I Repplier has been placed in charge of the new branch and will have two assistants and four nurses the latter under the direction of Miss Alice O Halloran. The dispensary will be open from 10 to 12, on Mondays, Tuesdays and Wednesdays A staff of visiting nurses will investigate conditions in patients' homes and such applicants as are found to be in need of extended treatment will be entered at the Mount Alto Sanatorium

TEXAS

New Clinic to Open.—A free surgical clinic is to be located at the Kenney Sanatorium San Antonio, the latter part of December Ten rooms of the new fifty room addition to the sanatorium will be set aside for the treatment of cases from this clinic

Medical Library Inaugurated—The Dallas County Medical Society has started a library in the Southwestern building which is open to physicians and surgeons of Dallas At present the library contains about one hundred medical journals and standard books of reference on various subjects in medicine

Hospital News—Contracts have been awarded for the erection of a fourteen room hospital for Dr R M Prather, Beeville ——Plans have been approved for the improvement and enlargement of the Temple Sanitarium to cost about $40,000 ——Plans are being considered for the remodeling of the Arlington Hotel, Marlin, and its conversion into a hospital

GENERAL

New Officers of Southern Medical Association—At the sixth annual meeting of the Southern Medical Association held in Jacksonville Fla November 12 14 the following officers were elected president Dr Frank A Jones Memphis, Tenn , vice presidents Drs Stuart McGuire, Richmond Va and J D Love, Jacksonville Fla and secretary treasurer, Dr Seale Harris, Mobile Ala Lexington, Ky , was selected as the next place of meeting

Mr Flexner with General Education Board—The General Education Board of 17 Battery Place, New York announces that Mr Abraham Flexner has become a member of its staff Mr Flexner is the author of The American College" (1908), and of the bulletins on Medical Education in the United States and Canada" (1910) and 'Medical Education in Europe' (1912) issued by the Carnegie Foundation for the Advancement of Teaching

The Congress on Mental Hygiene.—This organization which was in session during the last week at the College of the City of New York excited a great deal of interest and was not without practical results An appeal for subscriptions was made to further the plans for a nation wide educational campaign on mental hygiene which resulted in the announcement that an unnamed philanthropist would give $50 000 toward an endowment fund for the purpose provided $200 000 could be raised from other sources A large part of the hoped for endowment would be applied to the establishment of research laboratories and hospitals in various parts of the United States where investigations in regard to the causes and cure of insanity can be carried on extensively

Cholera—Reports to the U S Public Health Service and press reports indicate that cholera is present to a very serious extent in various parts of the world, the most menacing situation perhaps being in the war zone in Turkey Official information concerning the cholera is meager or absent, but the belated and imperfect press reports indicate that cases are occurring in large numbers particularly among the Turkish and Bulgarian troops in the field and fortifications near Constantinople and also among the refugees in the city of Constantinople Some newspaper reports give the number of cases occurring daily as up in the hundreds or even thousands It is also reported that the troops of the allies contain many victims of the disease On account of poorly organized medical and sanitary forces poor equipment lack of food supplies etc the epidemic may assume tremendous proportions On account of poor communication and probable suppression of news the exact conditions cannot be stated ——No cholera was reported from Italy during the past summer except at Cagliari Sardinia where about seventy cases have occurred since August 1 ——The disease is present in many places in Japan but no large outbreaks have occurred and public water supplies apparently are not infected ——The disease is also widely scattered throughout Southern Asia The Public Health Service is carefully watching the situation and taking necessary precautions to prevent the importation of the disease from Europe Reduced immigration and tran [illegible] and th [illegible] car [illegible] inspection of immigrants from [illegible] European p[illegible] before embarkation at Europ[illegible] the au[illegible]ties to keep the situation w[illegible] entrance of cholera into the

The large number of cases in the war zone, however, affords a serious focus of infection from which the disease may spread to a considerable extent throughout Southern Europe and so to the United States

Clinical Congresses—The week of November 11 was most notable in New York for medical and surgical activity In addition to the third annual session of the Congress of Clinical Surgeons of North America, many other organizations concerned with subjects pertaining to medicine and surgery held meetings The Congress of Clinical Surgeons was perhaps the largest assembly of surgeons that the world has ever witnessed, there being over 2,600 registrations The days were devoted to clinics and the evenings to scientific meetings There were as many as 180 to 190 clinics in progress and 300 to 800 operations performed daily One of the clinics most largely attended was that given by Mr W A Arbuthnot Lane of London at the new Policlinic Hospital when between four and five hundred were present in the amphitheater The clinics were so arranged that each visitor could see the most possible of the work being done in his specialty The scientific sessions were held in the ball room of the Waldorf Astoria with the exception of the Thursday evening meeting which was held in the Academy of Music, in Brooklyn, where the congress was the guest of the King's County Medical Society At the closing executive session of the congress resolutions were presented by Dr Franklin H Martin recommending that a special college of surgeons be established with power to grant a supplementary degree to the degree of medicine, which should be a fellowship in the proposed college This would be equivalent to a post graduate degree similar to the F.R C S of Great Britain Resolutions were also passed recommending a campaign of publicity on the subject of cancer of the cervix and a committee of five, consisting of Drs Thomas S Cullen, Baltimore, Howard C Taylor, New York City, C Jeff Miller, New Orleans, F F Simpson, Pittsburgh, and E C Dudley, Chicago, was appointed by the president to disseminate this information by having articles written to be published in the daily press or weekly and monthly magazines as might prove most expedient. The membership of the congress was so large that some method of limiting it to 2,000 members is under consideration The officers elected for the following year were president Dr George Emerson Brewer New York vice president, Dr W W Chipman, Montreal, general secretary, Dr Franklin H Martin Chicago, general treasurer, Dr Allen B Kanavel, Chicago, and chairman of the committeé on arrangements for 1913, Dr E Wyllys Andrews, Chicago The nominating committee recommended Chicago as the next meeting place

FOREIGN

The Red Cross at the Seat of War—The Italian Red Cross expedition from Bari consisted of ten physicians, forty nurses and 150 beds with full equipment, according to the *Policlinico* This expedition went to Montenegro and a similar expedition to Greece The Red Cross of Montenegro is collecting subscriptions to fit out an expedition, and the Italian society is also equipping at Turin a complete ambulance service to proceed at once to Montenegro The German Red Cross has equipped three expeditions and a large number of German physicians have gone from Germany to the seat of war. Drs A Dilger and A. Meyer of Heidelberg, with Professor Colmers of Coburg have gone to Bulgaria, with Drs Kirschner and Schubert From Switzerland have gone to Servia Drs Stierlin Socin and Vischer of Basel, with several Danish physicians Professor Coenen of Breslau has gone to Greece, and Drs Liebert and Hitzler have gone to Turkey The Austrian Red Cross has also sent expeditions and materials to Montenegro and Bulgaria It is stated that the officers of the Austrian society have been authorized to spend up to $40,000

LONDON LETTER

(From Our Regular Correspondent)

London, Nov 9, 1912

The National Insurance Act

The new offer of increased remuneration to the physicians by the government (described in my previous letter) is receiving the careful attention of the British Medical Association The council has issued a report to the divisions and representative body in which it is pointed out that a new situation has arisen, though many of the association's demands have not been granted With regard to the income limit of ten dollars a week for insured persons, which it will be remembered was one of the association's "six points," the regulations of the act require the surrender of the principle of central bargaining and leave to the profession in each area to obtain such an income limit as they desire and are strong enough to enforce. Another of the cardinal points is that all questions of professional discipline should be decided exclusively by a body or bodies of physicians While this demand has not been completely met an endeavor has been made to satisfy the desires of the profession while meeting the public demands for some representation of public interests on the tribunal established to hear complaints in which physicians are involved The procedure in the case of charges brought by one physician against another and of charges brought by a patient against a physician, or vice versa, is explained in the regulations The report concludes that while the proposed tribunal appears to offer a measure of security for a fair inquiry no regulations can be satisfactory which do not provide for right of appeal to a medical tribunal With regard to the amount of remuneration the government's last offer is a capitation fee of two dollars from which deduction of thirty six to fifty cents will be made for drugs while the association demands the same amount without any deduction for drugs

The British Medical Association has addressed a letter of inquiry to the Chancellor of the Exchequer, Mr Lloyd George asking him to elucidate further several points in his recent address to the insurance commissioners, embodying his last offer (reported in my previous letter) The increased services of which he spoke mean an increased service as compared with that which has been obtained in lodge practice in the past or which the great majority of the insured in view of their restricted means could not afford to obtain on private lines The standard which it is hoped that the physicians attending insured persons will reach and maintain is that which the best opinion in the profession itself would expect from a general practitioner in his ordinary work The government fully recognizes that the professional instinct of the majority of physicians will lead them without further stimulus to do all that can reasonably be expected in the interest of their patients With regard to the "modern methods of diagnosis" mentioned in his speech, the chancellor explains that physicians will not be expected to undertake work requiring skill and experience beyond that which the ordinary general practitioner can properly be expected to possess If methods of investigation beyond his scope are necessary, he will only have to advise the patient as to the steps he should take The physician will be expected to avail himself of all such facilities in the shape of expert assistance in investigations useful for proper diagnosis and treatment In so far as such facilities do not exist, the government hopes that means will be found for encouraging their development and organization in due course

A National Memorial to Lord Lister

At the Mansion House (the official residence of the Lord Mayor of London) a large and influential meeting was held for the purpose of establishing a fund for a memorial for the late Lord Lister It is proposed that this shall take the form of a medallion in Westminster Abbey, a monument in the metropolis and an international Lister Memorial Fund for the advancement of surgery The Lord Mayor presided and there were present some of the most eminent men in science (Lord Avebury, Sir Archibald Geikie, *president of the Royal Society*) in medicine (Sir Rickman Godlee, president of the Royal College of Surgeons, Sir Thomas Barlow, president of the Royal College of Physicians, Sir Francis Champneys, president of the Royal Society of Medicine, Professor Saundby Sir William Osler, and Prof Howard Marsh), and in politics (Lord Haldane, the Lord Chancellor and Lord Cromer)

The Automobile Death Roll

The automobile peril described in a previous letter to The Journal continues to exercise the public and has led to questions in the House of Commons Recent figures show that up to Oct 7, 1912, 118 people were killed in the streets of London this year On one day, September 19, as many as four persons were killed Replying to a question, Mr M'Kenna, the Home Secretary, said that if, as a result of coroners' inquiries, criminal negligence were proved, proceedings would be taken It was pointed out that at coroners inquests the motor bus companies were always represented by lawyers, whereas the relatives of the persons killed were generally too poor to be legally represented He said that the public has the protection of the coroner and jury When asked why motor vehicles were permitted to travel in the streets at excessive speed, seeing that the law provides that no motor vehicle should travel at a speed dangerous to the public, he replied that, in 1911, 893 drivers of motor cabs or omnibuses and 3,556 drivers of other motor vehicles were prosecuted in London for dangerous driving and that he was issuing instructions for the more stringent punishment of dangerous, negligent and reckless driving

Maternity Benefit in Australia

The Federal Senate of the Australian Commonwealth has passed the third reading of a bill providing for the payment of a bonus up to a maximum of $25 in respect of every child born in Australia of white parentage The payment has already begun This sum is much greater than the maternity benefit in the old country provided for by the national insurance act, which amounts to only $7 50, but it must be borne in mind that here the purchasing power of money is much greater than in Australia

Death Under Stovain

A man, aged 68, has died under spinal anesthesia induced by injection of stovain for an abdominal operation at St Thomas' Hospital After the operation had been satisfactorily performed his breathing became shallow, and although artificial respiration was resorted to and the heart was massaged, death took place in a few minutes At the inquest the anesthetist explained that he had administered stovain in 350 cases and that this was the first patient he had lost

PARIS LETTER

(From Our Regular Correspondent)

Paris, Nov 1, 1912

Personal

Dr Bégouin, *agrégé*, has succeeded Professor Chavannaz as professor of clinical gynecology at the Faculté de médecine of Bordeaux

The death is announced of Dr Henri Dor, aged 78 Dr Dor was born at Vevey, Switzerland, and had been professor of ophthalmology at the Faculté de médecine at Berne In 1876 he went to Lyons where he founded an independent eye clinic and the *Revue générale d'ophthalmologie*

Dr Paul Segond, professor of clinical surgery at the Faculté de médecine de Paris, has died of uremia at the age of 61 Dr Segond was the son of Dr L A Segond He received his medical degree in 1880 and three years later became *agrégé* of surgery and surgeon of the hospitals of Paris In 1905 he obtained the chair of operative medicine and in 1907 he was named professor of clinical surgery, succeeding Professor Terrier Since 1909 he had been a member of the Académie de médecine and last year was president of the Congres français de chirurgie Paul Segond wrote little but he possessed rare qualities as a surgeon He had specialized in gynecologic surgery and through his facility in vaginal operations had perfected considerably the removal of uterine fibromas through the vagina

Annual Meeting of the French Surgical Society

The twenty fifth meeting of the Association française de chirurgie was held in Paris, October 7 12, with Professor Delorme, medical inspector general of the army health service president The meetings of the congress as usual were well attended not only by French surgeons but by surgeons from abroad

PRACTICE OF SURGERY IN WAR

In his opening address the president regretted that no place is now given by the society, as formerly, to the subject of surgery in war He gave a summary of present practice, which in some respects differs from ordinary surgery as has been clearly shown in recent wars One of the clearest examples is laparotomy in wounds of the abdomen by small projectiles In the South African war leading surgeons were sent by the British government to the field of battle and they were surprised at the treatment of these wounds Spontaneous healing was permitted systematically instead of direct intervention Operations were done with the same care and skill as in hospitals in large cities, but the mortality among those operated on was greater than among those who were not operated on after being wounded This was the experience in Cuba and in Manchuria, and can readily be accounted for It is not possible to have the same mastery over conditions on the battle field that one can have in a regular hospital and an abdominal wound by a bullet from a distance is not so severe as one from the muzzle of a revolver, finally in adding a new traumatism to one which already exists the surgeon interferes with spontaneous encapsulation and is liable to spread infection

Surgery in war should have simplicity as its end Delorme although he believes in intervention at once in cases of severe wounds of the abdomen lungs or heart as a general rule nevertheless considers that in war intervention is contra indicated

DIAGNOSIS AND TREATMENT OF CICATRICIAL STENOSIS OF THE ESOPHAGUS

There was an interesting discussion as to the relative value in diagnosis of skiagraphic and fluoroscopic examination compared with esophagoscopy According to Dr Cuisez of Paris the Roentgen rays give two kinds of information with the use of bismuth wafers they show the location of the trouble and with bismuth lactate they show the form and size of the stenosis The fault of the rays is that they do not show the nature of the stenosis Esophagoscopy alone can do this As to treatment one obtains the impression on reading the literature that when catheterization is impossible in the usual way surgeons resort to severe operations which could have been avoided if they had tried dilatation with esophagoscopy which according to Cuisez succeeds in 95 per cent of cases and when ordinary catheterization is impossible catheterization from below should be employed through a large opening in the stomach Dr Moure of Bordeaux believes that in careful hands simple methods usually give good results but in severe cases one should not wait too long before making a stomach opening for gastrostomy often permits catheterization and dilatation from below at the same time saving the patient from death by inanition According to Dr Depage of Brussels, retrograde dilatation is one of the best methods provided that the stomach opening is large Professor Forgue of Montpellier emphasized the usefulness of gastrostomy, as there are many constrictions impassable until gastrostomy has been done Dr Delagenière of Mans also expressed the opinion that the stomach operation has great importance Under certain conditions it is enough to open the stomach, permitting complete relaxation of the esophagus to overcome the stenosis Professor Villar of Bordeaux, who described the first esophagostomy by the posterior mediastinal route in 1802 is of the opinion now that this is an operation to be avoided In fact severe operations for impassable stenosis ought to be discarded in favor of gastrostomy According to Dr Berard of Lyons one should always begin in examining a patient by fluoroscopy and skiagraphy for no matter how desirable esophagoscopy is there are times when it cannot be done This likewise was the opinion expressed by Professor Roux of Lausanne according to whom it is easier for an ordinary practitioner to open the stomach than to employ the methods of the specialists Dr Moure although a specialist, was unwilling to say that esophagoscopy is a panacea, because failures have been attendant on its use and even death has been caused

EXAMINATION BY ROENTGEN RAYS IN SURGICAL AFFECTIONS OF THE STOMACH AND INTESTINES

Drs Béclère of Paris and Mériel of Toulouse said that examination by Roentgen rays of the stomach and the intestine is the best method for showing the location the relations the form the dimensions and the muscular functions of a large part of the alimentary tract Latent ulcers are thus shown beginning stenoses and tumors which ordinarily escape palpation To clinical examination the Roentgen rays bring an element of exactness in the diagnosis of lesions taking the place of exploratory laparotomy and by permitting earlier intervention they make surgical success possible in more cases with more lasting cures Nevertheless Professor de Quervain of Basel has shown the mistakes to which a Roentgen ray examination may lead and has pointed out that this method has not superseded the clinical examination for a simple examination with one or two hands often corrects errors which would have been made had the evidence of the rays alone been depended on In regard to the stomach, for instance exaggerated peristalsis usually an indication of organic pyloric stenosis may be simulated by involuntary contractions of the stomach such as are found in tabes Ulcers and cancer located high near the cardia escape ordinary investigation although it is easy to demonstrate them if the patient is placed in the right lateral decubitus or in a slanting position with the head low The defective image of the pyloric region the most important sign of cancer here often results from insufficient emptying of the stomach before the test is made In cases of doubt examination in the right lateral position is an important adjunct In other cases the defective image is clearly indicative of a tumor of the kidney spleen intestine pancreas or one starting from the gall bladder As for the large intestine diagrams are often more difficult to interpret than those of the stomach and it is not advisable to depend too much on bismuth injection for determining the form and the position of the large intestine The method of choice is the administration of bismuth by way of the stomach with examination after from eight to twenty

Dr. Robert Fields Library
C. M. C. Medical College

four hours Numerous mistakes are made in the diagnosis of stenosis The tapering form of the fecal mass, so frequent as a rule in the lower part of the colon, should not be interpreted as a sign of stenosis unless it recurs regularly in several skiagrams at the same place Dr Girard of Geneva calls attention to toxic symptoms following the use of bismuth subnitrate in skiagraphy He prefers to use zirconium oxid although its opacity is a little less than that of bismuth Barium sulphate recently has caused severe symptoms probably on account of impurities Professor Hartmann of Paris is of the opinion that the stomach does not have the exact position which skiagrams indicate He advises interpreting them with careful attention to anatomy, for every surgeon knows that in some wounds of the abdomen in which the intestine alone is involved, the stomach also would have had to be wounded if it were as low as the skiagram shows it to be. It is probable that the weight of the bismuth has an effect. In intestinal work, Hartmann prefers fluoroscopy, but it is necessary here to be on one's guard against intestinal contractions which under the influence of bismuth simulate a stenosis which does not exist Bismuth should be taken by the mouth and examinations should be made at half hour intervals that its retardation or stopping may be observed Bismuth injection should not be used excepting for affections located low in the pelvic colon

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Nov 2, 1912.

Clinical Position of So Called Genuine Epilepsy

At the annual meeting of the German Neurologic Association, recently held at Heidelberg, the still unsolved question of the existence of genuine epilepsy was discussed by the distinguished investigators Professor Redlich of Vienna and Binswanger of Jena According to Redlich, true epilepsy, in the ordinary sense, cannot be etiologically distinctly defined, at the most, an artificial boundary line can be drawn in this way Neither does the form of attacks give any certain indication for the separation of genuine from organic epilepsy Paralytic phenomena after the attacks, or symptoms of defective brain action in the intervals are more frequent and more intense in organic epilepsy, but occur also in the ordinary epilepsy Permanent indications of mental defects (epileptic dementia) are very common in ordinary epilepsy, but may be absent, they also occur, on the other hand in organic epilepsy if it had its beginning in childhood or youth In the organic epilepsy there are found, in addition to the focal affections, diffuse changes, which may also occur in so called genuine epilepsy This disease also has a pathologic anatomy, and there are transitions between the two forms The best plan is to drop altogether the name genuine epilepsy" and for the present to define only the chronic form of epilepsy Opposed to this there is acute epilepsy and cases of occasional epileptic attacks The latter have a variable significance In part of the cases there is possibility of a transition to chronic epilepsy It is important in future to study the individual predisposition to epilepsy originating under different conditions from the varying capacity of the brain for the epileptic reaction and to study the pathogenic conditions under which the epileptic seizure develops In this way, actual insight into the pathology of epilepsy might be obtained

THEORIES OF EPILEPSY

According to Binswanger, the clinical position of so called genuine epilepsy affords at present opportunity for only a difficult and incomplete discussion There are two directions in which the conception of "epilepsy' is progressing The one is concerned almost exclusively with an anatomic and etiologic demonstration, and has established the view that the entire field of epilepsy must be separated from the functional neuroses and be classed with the organic diseases of the brain The other direction retains the clinico symptomatologic conception According to the first view the pathologic process in epilepsy is a chronic progressive one, which is manifested less in the seizures than in the various symptoms which occur during the intervals and in the progressive mental decay Certain clinical facts however, do not harmonize with this conception Only part of the cases follow the chronic progressive course with mental deterioration (epileptic dementia) Further, there is a group in which a mental change without doubt occurs which however does not consist in a deficiency of the mental processes, but in a peculiar change of character These psychopathologic manifestations are sometimes stationary sometimes they are subject to considerable variations, and occasionally they completely disappear In the latter case it can generally be established that they were directly related to the paroxysmal pathologic condition

Then there is a form of epilepsy, hitherto underestimated in its frequency and importance, which aside from the epileptic paroxysm or its equivalent, affords no evidence of any sort of psychic abnormality This group includes people who rank intellectually very high The majority of those so afflicted carry on their business and show no retrogression of their mental powers up to an advanced age. Further there are epileptics without dementia who may be regarded as having entirely recovered According to Binswanger's own experience the number of these is even greater than has been estimated Quite natural reasons (the disinclination of the patients to speak of their previous affection) make it difficult for us to obtain an exact numerical insight into this important question

Considering the above clinical facts, the other theory of epilepsy regards the epileptic convulsive paroxysm as the most important in the clinical picture, and classifies under this disease only those cases in which at some period of life genuine epileptic seizures have occurred Simple as this classification may be in the majority of cases of epilepsy, it is very difficult in the borderland cases The groups of psycho asthenic convulsions, of frequent slight attacks of narcolepsy, and emotional brain storms surely, in the majority of cases, do not belong to this conception of epilepsy

ANATOMIC BASES OF EPILEPSY

The adherents of the purely anatomic epilepsy base their views almost exclusively on the investigations of Alzheimer, who has shown that in about 40 per cent of all cases of genuine epilepsy there is a peculiar pathologic anatomic lesion, which should be designated as Alzheimer's gliosis It affects the most superficial layers of the cortex, and particularly the cortical layer of the spinal cord and the layer of the small pyramidal cells It is characterized by the fact that the increased gliomatous tissues to a certain extent fit into the architecture of the cerebral cortex Alzheimer considers the defects of tissues and the consequent epileptic dementia as a result of the epileptic seizures, a conception which Binswanger has advocated for years Accepting these data, one is justified in retaining the anatomic-etiologic group of epilepsy of organic origin, to which only those cases should be added in which macroscopic and microscopic recognizable lesions of the brain have caused the epileptic affection These are in particular retarded development, such as diffuse lobar and focal sclerosis, fetal and post fetal inflammatory degenerative processes, and acute focal affections of the nature of infectious encephalitis They all may lead to idiocy and imbecility with epilepsy, or to cerebral infantile paralysis with epilepsy Still, epilepsy may occur as a result of focal lesions due to acute infectious encephalitis, without retarded mental development

The anatomic bases of the epilepsy may be disclosed in some of the cases by the peculiar way in which the epilepsy develops or by distinct symptoms in the intervals and after the paroxysms In other cases the infectious encephalitic affection remains completely concealed during life Under organic epilepsy, according to the clinical etiologic point of view, may be included the toxic, traumatic, chronic infectious and arteriosclerotic epilepsies But even in these groups anatomic changes may be recognized, which certainly have some influence on the development, as in traumatic epilepsy A sharp separation of organic epilepsy is consequently, as a general rule, impracticable Only one group is left, that in which the epileptic disease has developed on the basis of a hereditary and congenital predisposition, or one acquired in early childhood without external cause In some cases the conditions of the origin of this constitutional form of epilepsy are still entirely unknown Yet, certain microscopically demonstrated hypoplasias of the brain permit the conclusion that in these constitutional forms finer morphologic defects in development play a rôle Moreover, it is very probable that the sclerosis of the cornu ammonis, which is found in 50 per cent of the cases of genuine epilepsy, belongs in this group of primary hypoplastic pathologic processes

DISTURBANCES OF A DYNAMIC FORM

There still remains a group of uncertain etiology, which may, for the present, be designated as a purely dynamic form This term is based on the assumption that the epileptic pathologic process, which Nothnagel called the "epileptic transformation" depends on a disturbance of the dynamic equilibrium of the central nervous system, a pathologic counteraction of exciting and inhibiting processes within the functioning organs These disturbances of dynamic equilibrium lead to the epileptic paroxysm, which in the sense of Jackson and Gowers may still be regarded as a process of discharge of a condition of extreme tension These dynamic disturbances, which in the completely developed epileptic convulsive attacks set in motion a peculiar epileptic mechanism, and in the incomplete attacks only a part of the same, may be, moreover, caused by the most various injurious influences, acting as a rule in a chronic manner, sometimes by circumscribed, more or less extensive foci either within or outside of the brain and sometimes by toxic or general traumatic injuries which occasion this specific transformation by means of chemical disturbances of nutrition within the functioning cortical substance Thus it is explained that in spite of the most various causes a disease can develop which with regard to its origin and course presents the most manifold individual variations, but on account of the common faculty of characteristic paroxysmal symptoms may even to day be regarded as a clinical entity

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Oct 20, 1912

The Program of Medical Lectures at the Vienna University, 1912 1913

In the winter term of the Vienna medical school there will be given 408 different lectures and classes for students and postgraduates, eleven more than last year The number of lecturers is also high, there being thirty two ordinary professors ninety four extraordinary professors, and 152 privat docents and assistants It is interesting to see how these numbers are divided among the various branches of our art There will be given four classes in history of medicine (which of late has become a favorite study here), twelve in histology and anatomy, fourteen in physiology, thirteen in medical chemistry, thirty six in pathology and pathologic anatomy, eleven in materia medica, 102 in internal medicine, nineteen in laryngo rhinology, nineteen in pediatrics, thirty nine in surgery, eleven in dentistry, thirty two in otology, thirty one in ophthalmology, forty two in gynecology and obstetrics, forty two in dermatology, including syphilis, twenty four in psychic medicine and seventeen in forensic, social and hygienic medicine The increase in classes for specialists in otology rhinology and laryngology is notable in late years The number of regular students at the medical school during the last (summer) term was 2,057, against 1,880 during the preceding summer term among them were 125 women (ninety eight in the corresponding period of 1911) The constant increase of medical students during the last twelve years is noted, and is stronger than the increase of the population in this country On the other hand, on account of the present war which requires military service from all able bodied men in the Balkan States, we expect for the coming term a much smaller number of students from those countries Otherwise, we would again encounter the usual difficulties of accommodating all those desiring to work in our medical and scientific institutions, which have led to energetic protests on the part of students against the government's parsimony in this particular branch

Honors to Professor Kassowitz

The well known specialist for diseases of children, Professor Kassowitz, recently celebrated his seventieth birthday and was the recipient of numerous honors on this occasion The official congratulation took place at the meeting of the pediatric section of the Medical Society of Vienna when the Faculty of Medicine the Senate of the University, the Hungarian Society of Physicians and numerous corporations tendered their congratulations by delegates A *Festschrift* was published in honor of the scientist who on this occasion delivered a most interesting lecture on "Facts and Theories and Their Influence on Natural Science and Medicine" He emphasized the necessity of being on the lookout for unverified popular theories Professor Kassowitz is also at the head of the anti alcohol movement in this country

An Annex to the Anatomic Institute

The number of students who can be accommodated in the anatomic institutes of Vienna is altogether out of proportion to the number who apply for admission The government has hitherto paid no attention to the demands of the medical faculty and the students who asked for new facilities but now has granted an appropriation for a third anatomic theater capable of holding like the present two 250 students making a total capacity for 750 students In one or two years the institute will be enlarged by adding a large museum and laboratory hall At a meeting of students the addition of the two dissecting rooms was declared insufficient and the erection of an appropriately large institute was urgently demanded •

Marriages

WILLIAM HENRY BEARDSLEY M D Springfield Mass to Miss Anna Jackson Harkness of Springfield Vt October 29

FREDERICK N HENDERSON M D Rockville Md., to Miss Gussie Glenn Lamar at Memphis Tenn., November 3

HENRY DAWSON FURNISS, M D, New York City to Miss Ruth Kellogg Pine of Troy, N Y November 18

WILLIAM EDWARD HARTIGAN M.D to Miss Gertrude Gladding both of Norwich N Y November 7

ALFRED LAWRENCE RHOADS M D Scranton, Pa to Miss Lou Engles of Stroudsburg Pa, November 12

ROBERT PAGE COOK M D Front Royal Va to Miss Nellie V Jones, at Front Royal November 2

EDWARD HARRIS GOODMAN M D Philadelphia to Miss May Dudley of Camden N J, November 9

JAMES ALEXANDER CRAIG M D, Cary, Ind, to Miss Mary Arnold of Lebanon Pa, November 12

ROBERT LEWIS RHODES, M D Roanoke, Va, to Miss Margaret Farmer of Louisville, Ga, October 25

BENJAMIN FRANKLIN SAYLOR M D, Redding Cal, to Miss Alice Taylor of St Louis November 7

GEORGE RINEHART M D, Cassville, W Va to Miss Lena Grace Core at Cassville, November 8

JUDSON E HAIR M D to Miss Ivy J Kinney, both of Baltimore in Philadelphia, October 23

ABRAHAM POTASNIC, M D, Meridian, Miss, to Miss Dora Cohen of Milton, Fla October 6

JACKSON R CAMPBELL, M D, to Miss Mary Anderson, both of New York City, November 7

THOMAS RODNEY CHAMBERS M D, to Miss Martha V Sisson both of Baltimore, November 6

JUDSON TEETER M D to Miss H Elizabeth Seng, both of Pleasant Hill O, November 10

WESLEY HARTMAN RENNIE M D, U S Navy, to Miss Lita Jaques of Chicago, November 7

FRANK K ROY, M D Clarence, Mo, to Miss Pearl Keller of Kansas City Mo November 2

HARRY JAMES HOAG M.D to Miss Elizabeth Dunn, both of Mora, N Mex, September 25

FRANK ASBURY OSINCUP, M D, to Miss Mary Wodring, both of Waverly Ia November 7

GEORGE B FLETCHER M D, Lonoke, Ark, to Miss Vera Blood of Grayville Ill October 23

WILSON J FERGUSON, M D, to Miss Willa Burke, both of Sedalia Mo October 31

WILLIAM FRY, M D to Miss Ruby I Thompson, both of Baltimore October 26

JOSEPH C FRIEDMAN M D, to Miss Beatrice Shaffner both of Chicago, November 12

Deaths

John William Mallet, M D Tulane University New Orleans 1868 a member of the Medical Society of Virginia and a chemist of distinction died at his home in Charlottesville November 7 from pulmonary embolism aged 80 He was graduated from the University of Dublin in 18[illegible]3 and a year later became assistant professor of analytical chemistry at Amherst (Mass) College and from 1855 to 1860 he was professor of chemistry in the University of Alabama Mobile During the Civil War he served in the Confederate service and was in charge of the ordnance laboratories At the close of the war he was made professor of chemistry in the University of Louisiana and later professor of analytical industrial and agricultural chemistry at the University of Virginia active from 1872 until 1908 and professor emeritus in [illegible] that time Dr Mallet had also served at various times as professor or lecturer at Johns Hopkins University Baltimore the University of Texas Galveston and Jeff[illegible] M[illegible] College and for three terms was a member [illegible] at [illegible] Commission He had been hon[illegible] the University of Göttingen [illegible] and Mary College, the University of Mississippi, Princeton University, Johns Hopkins University and the University of Pennsylvania Dr Mallet was a frequent contributor to the chemical literature, he was a member of scientific bodies at home and abroad and was one of the most distinguished chemists of the United States

Robert Fletcher, M D M R C S, England, 1844, principal assistant librarian in the library of the surgeon general's office, Washington, D C, since 1886, died in his apartment in Washington, November 8, aged 89 Dr Fletcher was born in Bristol, England, March 3, 1823 He served throughout the Civil War, first as surgeon of the First Ohio Volunteer Infantry, then successively as assistant surgeon, and surgeon, U S V, and was mustered out in 1867 He was a member of the American Medical Association, Medical Society of the District of Columbia, National Geographic Society Philadelphia College of Physicians and other learned societies In 1910 Dr Fletcher was awarded the gold medal of the Royal College of Surgeons of England in recognition of his distinguished services in connection with the indexing of the catalogue of the Surgeon General's Library He was lecturer on medical jurisprudence from 1884 to 1886 and professor from 1886 to 1888 in the Columbian University, Washington, and later was lecturer on forensic medicine in Johns Hopkins University He was a frequent contributor to the literature of the history of medicine and anthropology

Franklin Buchanan Smith, M D University of Pennsylvania, Philadelphia, 1878, a member of the American Medical Association, once president of the Medical and Chirurgical Faculty of Maryland, and for several terms president of the Frederick County Medical Association, first health officer of Frederick City and County, Md, a member of the State Board of Medical Examiners since its organization in 1892, for ten years a member of the local U S Pension Examining Board, for eight years physician to Montevue Hospital, and for more than twenty years local surgeon of the Baltimore and Ohio and Pennsylvania systems, died at his home in Frederick, November 5, from typhoid fever, aged 56

Bradford S Galloway, M D University of Michigan, Ann Arbor, 1880, for twenty three years a practitioner of Leadville, Colo, chief surgeon of the Colorado Midland Railway for three years and local surgeon for the Colorado Southern Railway for twenty years who moved in 1901 to Denver and two years later to Goldfield, Nev, and had been for four years a resident of Los Angeles, died suddenly in a restaurant in that city, November 2, from embolism, aged 58

John Denham Palmer, M D University of Maryland, Baltimore 1872, of Jacksonville, Fla, a member of the Florida Medical Association formerly chief surgeon of the F, E and P Railroad, who took a prominent part in the yellow fever epidemics in Memphis, Tenn and Fernandina and Jacksonville, Fla, died in St Luke's Hospital, Jacksonville, from the effects of an accidental gunshot wound, November 3, aged 62

John T Mitchell, M D Jefferson Medical College, 1880, a member of the Missouri State Medical Association, for twenty five years a practitioner of Kansas City, professor of anatomy in the Western Dental College and lecturer in the Kansas City School of Pharmacy, died in St Luke's Hospital, Kansas City, November 4, from pneumonia, aged 65

James Stuart Dickey, M.D Queens University, Belfast, Ire, 1910, senior demonstrator of anatomy in his alma mater, professor of anatomy in the Western University, London, Ont, committed suicide in the pathologic laboratory of that institution September 21 by gas asphyxiation while suffering from melancholia, aged 30

Lucius Wadsworth Clarke, M D University of Vermont, Burlington, 1863 assistant surgeon of the Thirteenth Connecticut Volunteer Infantry until the close of the Civil War, for forty six years a practitioner of Cambridge Wis, and for two years president of the village, died at his home, November 3, from senile debility aged 81

John Thomas Duncan, M.D University of Toronto, Ont, 1882, of Toronto, for many years lecturer in anatomy at the Medical College for Women and oculist to the Western Hospital, who retired from practice about six months ago on account of bronchitis, died in California, November 4, aged 59

Lewis John Davis, M D University and Bellevue Hospital Medical College, 1899 of Watertown N Y, was found dead in his room in the Hotel Marlborough New York City, November 4, it is believed from the effects of an overdose of morphin, aged 45

William H Robinson, M D University of Pennsylvania, Philadelphia, 1868, for several years visiting physician to the Pottsville Hospital, a member and for several years president of the Pottsville City Council secretary of the Board of Health, and registrar of the State Department of Health, died at his home, November 4, from disease of the kidney

Lynn Boyd Graddy, M D University of Nashville Tenn, 1874, once president of the Tennessee State Medical Association and Nashville Academy of Medicine, for twelve years professor of diseases of eye, ear, nose and throat in his alma mater, from 1884 to 1888 a resident of Omaha, died at his home in Lexington, Tenn, November 11, aged 67

Louis S J Gessner, M D University of Heidelberg, Germany, 1858, assistant surgeon of the Thirty Seventh Ohio Volunteer Infantry during the Civil War, a pioneer practitioner of Sandusky County, O, died at the home of his daughter in Fremont November 4, from paralysis, aged 82

Walter Henry White, M D Boston University School of Medicine, 1882, a member of the American Medical Association, formerly president of the American Electro Therapeutic Association and associate editor of *Advanced Therapeutics*, died at his home in Boston, about November 6, aged 66

Marietta Huntington Crane Woodruff, M.D New York Medical College and Hospital for Women, New York City, 1874, one of the first women to practice medicine in New Jersey, died at her home in Boonton, November 6, from hemorrhage following an attack of coughing, aged 75

Randolph Littrell Collins, M D Medical College of Virginia, Richmond 1910, of Woodlawn Va, a member of the American Medical Association, died in the University Hospital, Richmond November 3, from peritonitis following an operation performed several days before, aged 25

Benjamin F W Urban, M D University of Pennsylvania, Philadelphia, 1869, court crier of Court No 2, Lancaster, Pa, clerk of the Quarter Sessions Court for two terms, a veteran of the Civil War, died at his home in Lancaster, November 3, from angina pectoris aged 66

Claudius Galen Treichler, M D University of Pennsylvania, Philadelphia, 1865 a member of the American Medical Association and a fellow of the American Academy of Medicine, died at his home in Honeybrook, Pa, November 2, from heart disease, aged 72

John Eugene Monroe, M D Cleveland University of Medicine and Surgery 1893, for nineteen years a practitioner of Orange, Mass, died in the Memorial Hospital, Worcester, Mass, November 5, after an operation for the removal of carbuncle aged 53

Frank Lincoln Hamilton, M.D University of Pennsylvania, Philadelphia 1893, a member of the Medical Society of the State of Pennsylvania and for eighteen years a practitioner of Chester, died at his home, November 4, from cerebral hemorrhage, aged 47

Charles C Knapp, M.D University of Tennessee, Nashville, 1893 a member of the American Medical Association and a specialist on diseases of the eye, died at his home in Zanesville, O, November 5 from cerebral hemorrhage, aged 48

Thomas Benton Marquis, M D Bellevue Hospital Medical College, 1877, since 1882 president of the local board of pension examining surgeons of Lisbon, O, died at his home, November 5, from uremia, following pneumonia, aged 58

Clarence Albert Baker, M D College of Physicians and Surgeons, New York City, 1886, health officer of the town of Brookhaven and physician of Suffolk County, died at his home in Yaphank, L I, New York, November 8, aged 50

Emory Strickler, M D Eclectic Medical Institute, Cincinnati, 1865, first superintendent of Schools of Harrison County, Va, a veteran of the Civil War, died at his home in Shinnston, W Va, October 25, from senile debility, aged 84

Leo H O'Meara, C M, M D Queens University, Kingston, Ont, 1911, formerly of Fallowfield and Ottawa, Ont, surgeon to the Algoma Central and Hudson Bay Railroad, was accidentally drowned at Hobon, Ont, November 2

Andrew Thomas Brenton (license, Iowa, 1887), an early practitioner of Sac City Ia, but for a few years past a resident of Florida, died at the home of his son in Havelock, Ia, October 26, from cerebral hemorrhage, aged 69

William Marmaduke Owen (license Jefferson County, Ala, 1887), a Confederate veteran and for forty years a practitioner of Texas, and Jonesboro, Ala, died at the home of his son in Dora, Ala., November 5, aged 77

Willard P Brickley, M D American Medical College, Cincinnati, 1856, one of the founders of the Physio Medical College of Indiana, Indianapolis, a resident of Madison County, Ind, for seventy years, died at his home in Anderson, November 10, aged 89

Homer Simpson Bell, M D Dartmouth Medical School, Hanover, N H, 1873, for many years a practitioner and town clerk of Granby, Mass, died at his home in Springfield, Mass, November 3, from diabetes, aged 61

Jacob Ellsworth Ernest, M.D Jefferson Medical College, 1892, formerly of Williamsburg, Pa, but since 1896 a practitioner of Johnstown, Pa, died in the Johnstown City Hospital, November 1, aged 48

Marion Francis Shaw, M D Bellevue Hospital Medical College, 1884, formerly health officer of Hood River County, Ore, died on his ranch near Hood River, October 31, from heart disease, aged 54

David Henry Agan, M D Bellevue Hospital Medical College, 1879, a member of the Medical Society of the State of New York, died at his home in New York City, November 6, aged 64

Joseph E Fopeano, M D Long Island College Hospital, Brooklyn, N Y, 1889, a member of the Medical Society of New Jersey, died at his home in Hoboken, October 4, aged 56

Thomas Stanhope Henry, M D Medical College of Virginia, Richmond, 1866, of Brookneal, Va, died November 11, at the ancestral home of the Henry family, Red Hill, Va, aged 80

Andrew H Diven (license, Oregon, 1889), a practitioner of Pennsylvania from 1861 to 1889 and thereafter a resident of Portland, Ore, died at his home, October 30, aged 76

William H Dorsey, M D Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897, died at his home in Griffin, Ga, October 26, from cerebral hemorrhage, aged 42

Simeon G Story, M D University of Toronto, Ont, 1893, one of the best known practitioners of Kent County, Ont, died at his home in Blenheim, November 4, aged 47

Henri Riedelle Thayer (license, Mass, act of 1894) for thirty five years a resident of Boston, died at his home, November 1, from senile debility, aged 93

James Edward Gregory, M D Illinois Medical College Chicago, 1905, a colored practitioner of Gainesville, Tex, died at his home November 7, from pneumonia

Edgar DuBois Biddle, M D Missouri Medical College, St Louis, 1880, of Patoka, Ind, died in a hospital in Chicago, November 7, from paralysis aged 55

Elwood MacDonald Blakely, M D Manitoba Medical College Winnipeg, 1907, was found dead in his office in Elm Creek, Man, about October 31, aged 30

Raymond Albert Young, M D University of Michigan, Ann Arbor, 1909, died at the home of his parents in Grand Rapids, Mich, November 2, aged 26

Henry George Small, M D College of Physicians and Surgeons, New York City, 1875, died at his home in Brooklyn, N Y, November 8 aged 60

Edmund H Packer, M D Homeopathic Medical College of Pennsylvania, Philadelphia, 1867, died at his home in Lowell, Mass, October 10, aged 68

William A. Edwards, M D Physio Medical College of Indiana, Indianapolis, 1898, died at his home in New Douglas, Ill, October 22, aged 41

William W Jones, M D Eclectic Medical Institute, Cincinnati 1881, died at his home in Utica, N Y, November 8, from nephritis aged 55

Joseph Pfeiffer, M.D University of Giessen Germany, 1853 died at his home in New York City, October 31, from senile debility, aged 85

Almond A Stuart (license Indiana 1897) was shot and killed in the door yard of his home at Fortville, Ind November 7, aged 68

Joseph W Kitten, M D Jenner Medical College Chicago 1906 died at his home in Chicago, November 2, from pneumonia aged 44

William Commons, M.D Medical College of Ohio Cincinnati 1863, died at his home in Union City Ind, October 27 aged 76

W C Ashley, M D Atlanta (Ga) Medical College 1884 died at his home in Ocilla, Ga, November 9, from nephritis

The Propaganda for Reform

In This Department Appear Reports of the Council on Pharmacy and Chemistry and of the Association Laboratory Together with Other Matter Tending to Aid Intelligent Prescribing and to Oppose Medical Fraud on the Public and on the Profession

DUFFY'S MALT WHISKEY

"Patent Medicine" or Poor Liquor—Which?

What is this widely advertised fraud sold as a consumption cure,' claimed to be the 'greatest known heart tonic and a preparation that 'builds up the nerve tissues tones up the heart gives strength and elasticity to the muscles and richness to the blood?" The answer to this question will be found to depend, apparently, on when it is asked

During the Spanish American war Duffy's Malt Whiskey qualified as a "patent medicine" by the payment of the special tax that was put on nostrums as a means of raising revenue In a circular issued at that time by the Treasury Department it was stated

> The Duffy Malt Whiskey Company have by evidence under oath filed in this office shown that their compound called Duffy's Pure Malt Whiskey is composed of distilled spirits in combination with drugs

On the other hand, even while the Federal Government was declaring the stuff a 'medicine," the Supreme Court of the state of New York decided that Duffy's Malt Whiskey was not a medicine but a liquor and that persons selling it would be required to pay the same excise tax and to procure the same liquor tax certificate that were required of the sellers of any other whiskey The way in which the New York courts came to pass on this question is an interesting chapter in patent medicine" history

THE PAXSON CASE

A New York City druggist named Paxson sold Duffy's Malt Whiskey without first having paid the liquor license The New York state excise department proceeded against the druggist for so doing Paxson's defense was that Duffy's Malt Whiskey was not a liquor but a medicine and it was, therefore, not subject to the liquor laws of the state of New York When the case came to trial the New York authorities called as witnesses three chemists Dr Joseph De Cuebucc, Dr Charles A Crampton and Dr Edward W Wheeler

WHAT THE CHEMISTS FOUND

Dr De Guebucc, who at that time was chief chemist in the Health Department of the City of New York testified that he had analyzed Duffy's Malt Whiskey and he reported in part

> I found the contents of the bottle to be whiskey with a little cane sugar added to it a sweetened whiskey I found no other ingredients My examination would have revealed any other ingredients present in quantities sufficient to be determined by chemical analysis '

Dr Crampton, the chief chemist of the Internal Revenue Bureau of the Treasury Department in Washington, reported his results in part as follows

> I have made an examination of the substance known as Duffy's Malt Whiskey I found it contained no medicinal ingredients outside of the alcohol in the whiskey It is whiskey of a very poor quality as a beverage it is not whiskey which according to the pharmacopeial standard has been aged The taste of this bottle is indicative of a rather poor quality of whiskey what is known as young whiskey or raw whiskey it has not the full flavor and aroma of an aged whiskey

Dr Wheeler a chemist of the New York state Department of Agriculture testified that he had analyzed Duffy's Malt Whiskey

> In my opinion there is no appreciable drug or medicine in Duffy's Malt Whiskey Th [illegible]

cent of solids in the bottle which I analyzed The solid was largely sugar There was coloring matter"

WHAT THE DUFFY PEOPLE CLAIMED

The courts assessed against Paxson a judgment of more than $700 Paxson then appealed the case to the New York Supreme Court, which refused to set the judgment aside and assessed him further costs for the refusal Then the Duffy Malt Whiskey people showed their hand They took up the matter and a motion for a new trial was argued on the ground that new and important evidence had been found In affidavits submitted by the Duffy Malt Whiskey Company, Clarence E Sherin, *president of the concern, declared that* Duffy's Malt Whiskey contained, in addition to alcohol, the following drugs

Fluid extract calumba (columbo)
Fluid extract hydrastis (golden seal)
Fluid extract pareira (Pareira Brava)
Fluid extract taraxacum (dandelion)

Dr Richard Curran, Rochester, N Y, declared under oath

> That he personally prepares the tincture made from the following drugs, viz Fluid Extract Calumba (Columbo) Fluid Extract Hydrastis (Golden Seal) Fluid Extract Pareira (Pareira Brava) Fluid Extract Taraxacum (Dandelion) under direction of the Duffy Malt Whiskey Company which tincture he knows to be used in the preparation of the medicinal compound known as Duffy's Pure Malt Whiskey His knowledge *that these medicinal agents are* used is because of the fact that he personally delivers the same to Walter J Duffy vice-president of the Rochester Distilling Company

He further declared

> That he himself personally makes the medicinal *tincture and* from his own knowledge says that the character of the product and its *effect on the system is in marked contrast with any straight* whiskey in fact he regards it as a whiskey in name only a medicine of the greatest value in fact

It will be noticed that the *amounts* of the drugs alleged to be put in the whiskey are not given Further affidavits were filed in the case from several Rochester physicians each of whom had some words of praise for this stuff

SOME SWORN TESTIMONIALS

Dr William B Conner regarded Duffy's Malt Whiskey "as a valuable curative agent" which he had "had occasion to use in his practice"

Dr W Hobart Curtis affirmed that 'the effect of Duffy's Pure Malt Whiskey is different from that of any other whiskey "

Dr Edwin S Hayward, Jr swore that he considered the stuff "a medicine of widely acknowledged value" and that it has been his habit to prescribe it "in cases where the activities have been at low ebb"

Dr Harry M Schall declared under oath that "on numerous occasions he has used Duffy's Pure Malt Whiskey in his practice"

Dr J Sherburne Read declared that 'Duffy's Pure Malt Whiskey has been used and prescribed by him for a number of years" Incidentally it may be mentioned that Dr Read at present is the director" of *the Okola Laboratory, a fraudulent* mail order medical concern operated by the Neal Adkin syndicate

Dr George W Goler, *who at that* time was health officer of the city of Rochester, declared that he 'has been informed of the drugs used in medicating Duffy's Pure Malt Whiskey *and with this information and his knowledge of the power of* such drugs, he is free to say that the quantity and quality of the medicines so employed substantially transform the liquor *from the condition of being purely a whiskey to a medicated* compound"

Dr John A Stapleton deposed that "he was made acquainted with the method of medicating Duffy's Pure Malt Whiskey and the drugs employed for the purpose" and was 'of the opinion that the liquor during such medication undergoes a decided change"

Dr. J J A. Burke swore that he was aware from the beginning that Duffy's Pure Malt Whiskey was being medicated' and further that he 'knew of the ingredients employed for the purpose and thought them good"

Dr Richard M Moore declared that he was "convinced that the liquor can *no longer* be considered a stimulant pure and *simple, but a medicated combination by the solvent power of* alcohol" [Italics ours—Ed]

Dr. William M Barron stated that "he knows the remedies *employed in medicating* Duffy's Pure Malt Whiskey" and "unhesitatingly considers that this whiskey is changed in a marked degree by the introduction of these drugs"

Thus did these *Rochester physicians solemnly declare that* Duffy's Malt Whiskey was a "patent medicine" and not a cheap whiskey Nevertheless, the analyses made by three *chemists, working independently, conclusively proved that there* were no drugs present in sufficient quantities to be demonstrable by chemical analysis! Again it should be noted that while the Duffy concern swore *that drugs were put into its* whiskey, it was careful to avoid giving any information regarding the quantities of the drugs that were alleged to be added

The state chemists of North Dakota *subjected this product* to chemical analysis and in the Agricultural Experiment Report for 1906 declared

> "Analysis indicates it to be nothing more than neutral spirits, colored and flavored The amount of solids is high because it has syrup added to make it 'smooth and give it flavor"

POLITICAL INFLUENCE PROTECTS A FRAUD

For years, Duffy's Malt Whiskey has gone out to the public *with the most flagrantly false and fraudulent claims* made for it on the wrapper around the bottle The government officials finally took action and in 1908 a quantity of Duffy's Malt Whiskey was seized on the charge of being adulterated and misbranded under the Food and Drugs Act What happened? It appears that the Hon James Breck Perkins, member of Congress from Rochester, at once "got busy"

At the time of the prosecution by the state of New York, Mr Perkins was attorney for the Duffy Malt Whiskey Company and it was he who filed the brief in behalf of the company in support of the motion for a new trial Mr Perkins at that time, was apparently highly incensed by the activities of the state authorities against Duffy's Malt Whiskey In closing his brief at that time, Mr Perkins expressed himself thus

> It does not seem to me that the officers who represent the state in any proceeding and certainly not in criminal proceedings are *required to exhibit so extreme a zeal*

Apparently zeal, in a public officer acting against large vested interests, however fraudulent, is something that Mr Perkins would not tolerate It is not surprising, then, that when the Department of Agriculture seized a large consignment of Duffy's Malt Whiskey, Congressman Perkins should rush to the rescue The incident was described somewhat fully by *Collier's* at the time According to that paper, Perkins wrote his first letter on the official stationery of the House Committee on Foreign Affairs of which committee he was a member It read in part

> The Duffy Malt Whiskey Company is controlled by our *most prominent and leading citizens and I trust matters can be adjusted in such a way as not to injure a long established industry'*

He wrote a second letter, it is claimed, this time on the official stationery of the Printing Committee In addition, letters were written by various other prominent politicians of western New York and a dozen personal visits were made to Washington No less than six different officers of the Department of Agriculture are said to have been written to The hearing was postponed time and again. Finally, it was set for a definite date but before *that time arrived it was, again postponed* This, it must be remembered was in 1908 In the latter months of 1910, The Journal attempted to get some information regarding the status of the case We were told that the case was still pending It is now almost 1913 and so far as we can learn, the case is still pending! *Collier's*, in closing its article regarding this disgraceful piece of political activity says

> "Consider, now, one question Was Perkins paid for what he did? Did he make that long hot trip from Rochester to Washington the night of July 16—Congress not being in session—from motives of public duty, or did he get money for it? If he

got money he is guilty of exactly the same crime as that for which Senator Burton of Kansas went to the penitentiary For the immediate activity of the Secret Service men there is no more pressing need than the investigation of whatever checks may have passed during the last eight months from the Rochester manufacturers of Duffy's Malt Whiskey (Walter J Duffy president) to the Rochester law firm of Perkins, Duffy & McLean (this latter Duffy being J P, son of Walter J)

"But whether Congressman Perkins has been guilty of a crime is not the point of this article What is important is to let all the people know how necessary is their constant vigilance and support to see that the Pure Food Law is carried out If you were an obscure subordinate in the Department of Agriculture or the Department of Justice, if you had no motive to proceed against a swindling patent medicine or an adulterated food except your own conscience, if your first move met with personal protest from the congressman who controlled your salary, your promotion, and your official existence, how soon would you grow tired? The enforcement of the pure food law needs all the encouragement and enthusiasm that the public can contribute, there is no trouble about the enthusiasm of the opposition—that is a matter of dollars and cents, and it is working twenty four hours a day "

"DUFFY'S ANNUAL"

Every bottle of Duffy's Malt Whiskey is wrapped in a large circular called "Duffy's Annual" This "Annual" consists, largely, of testimonials from laymen and physicians We have on file one issued in 1901 and another issued in 1911 There are noticeable differences between the two circulars In the earlier annual much is made of the statement that Duffy's Malt Whiskey contains no fusel oil, nothing is said on this point in the later circular The 1901 issue comes out frankly with the falsehood that Duffy's Malt Whiskey "cures consumption," etc In the 1911 circular the 'lie direct" has given place to the lie with circumstance" The earlier circular contains a long testimonial from Willard H Morse and the Duffy company at the conclusion of the testimonial adds

> Dr Morse is not only an M D and an F S Sc. but is a well known therapeutist and a consulting chemist of national reputation

The facts are that Willard H Morse is a professional testimonial writer who has issued fake analytical reports for some of the biggest frauds on the American market The title F S Sc." is one that is given—price $5 (1 guinea)—by a fraudulent organization in London that styles itself the Society of Science, Letters and Art This title is very popular with 'patent medicine" fakers

The earlier "Annual" recommends Duffy's dope for "painful and irregular periods"—pathologic states about which the later one says nothing The 1911 circular 'features" a testimonial from the "Hon Richard Curran, M D, formerly mayor of Rochester" This testimonial may carry weight with those who do not know that Dr Richard Curran is in the employ of the Duffy's Malt Whiskey Co He it was as we have shown who testified in May 1905, that he prepared the various drugs which were put in Duffy's Malt Whiskey But we have on file a letter written in 1910 by Dr Curran—and written on the stationery of the Duffy Malt Whiskey Company—in which he declares

> Duffy's Pure Malt Whiskey is not a patent medicine but a refined medicinal whiskey made from choice materials and complies with the test requirements of the United States Pharmacopeia

Does this mean that the Duffy product of to day is different from that sold five or six years ago? It would seem so Some of the more recent pamphlets sent out by the Duffy Malt Whiskey Company contain what purport to be analyses made by chemists One of these is from Joseph De Cuehuce who it will be remembered, when testifying in 1905 as chief chemist of the health department of the city of New York, declared that he found this product to be "whiskey with a little cane sugar added to it " But Dr De Cuehuce later became associated with the Lederle Laboratories and in that capacity he declared 'Duffy's Pure Malt Whiskey is free from added sugar "

We have been asked at various times whether the testimonials of Duffy's Malt Whiskey purporting to come from physicians are genuine Investigation of a large number of them indicates that the testimonials as now published are documentarily genuine Evidently the Duffy Company has found that it is no longer necessary to "fake" testimonials,[1] as it has done in the past

Of 104 physicians who had written testimonials for Duffy's Malt Whiskey, 5 are members of the American Medical Association, and 18 have written testimonials for other nostrums From our files it appears that some of the 104 testimonial givers are either advertising quacks or are connected with fraudulent medical concerns It is not difficult to estimate the scientific value of testimonials that come from such sources

CONCLUSION

We may accept the statement of the state chemists of North Dakota that the stuff is plain alcohol with syrup added to give it smoothness' and coloring added to make it look like whiskey or we may believe the federal chemist who declared it simply whiskey of a very poor quality " or we may think that Chemist De Cuehuce was right when he said it was 'whiskey with a little cane sugar added to it " or we may prefer Dr De Cuehuce's later pronouncement that the stuff is free from added sugar," again we may feel that Dr Curran's early declaration is worthy of attention and that Duffy's Malt Whiskey contains drugs and is a medicine' or possibly we may take Dr Curran's later statement that the product is merely a whiskey as defined by the Pharmacopeia But whether we consider Duffy's Malt Whiskey a 'patent medicine" or a low grade booze' makes little difference On one point we can agree unanimously the stuff is an impudent fraud As we have said elsewhere A high grade whiskey has but a limited place in therapeutics, Duffy's Malt Whiskey has none

ADVERTISING FAKES

This from the Pulaski County *Democrat* of Winamac, Ind November 14, is commented on editorially this week

> The *Democrat* received a few days ago a proposition to publish considerable advertising matter boosting a patent medicine called Nature's Creation,' which is asserted in the strongest language to be a cure for consumption The offer meant quite a sum of money to us, but we refused to have anything to do with it
>
> The reason for our action is that we do not knowingly advertise any article that is a fake and we have what we believe to be reliable and authentic information that this pretended cure is a fake, a fraud, and that it will *not* cure consumption therefore were we to advertise the stuff to do what it cannot and thereby induce ailing persons to depend on a worthless nostrum until death resulted, our own skirts could not be clean morally
>
> Our information is that this 'Nature's Creation now emanating from Columbus or Indianapolis or both was exploited in Chicago not very long ago as an absolute cure for syphilis but as the public became more and more interested in the subject of tuberculosis during the last four or five years the stuff has been changed to a consumption specific—probably more sale for it thus than for syphilis
>
> We have a list of forty five Columbus Ohio persons who are alleged to have taken this cure for consumption—and died we have not heard of any cured by it It might be the proper thing if suicide is the object '

Correspondence

Dr Robert Fletcher An Appreciation

To the Editor —With the death of Dr Robert Fletcher principal assistant librarian of the Surgeon General's Library for nearly thirty five years there passed away a mentor of medicine who was looked up to and honored everywhere for his intensive labors in medical bibliography his rare scholarship and that courteous and cheerful spirit of helpfulness which in the words of Dr Howard Kelly has endeared him to the entire profession of the United States " [illegible] when he died, his span of life, like Heberden's, extended over nearly a century, and with Heberden the scholar, as distinguished from the clinician, he had many points of resemblance In his lifetime, he had seen and met personalities so various and so widely separated in time as Sir Astley Cooper and Halsted, Daniel Drake and Sir William Osler, Emerson and the philosophers and poets of a later period A native of England, he had served his adopted country for fifteen years with distinction as an army surgeon during the Civil War and afterward, and he was buried at Arlington with the honors commensurate with the military rank he attained

---

[1] Some testimonials investigated [illegible] Journal [illegible]

Dr Fletcher was born in Bristol, England, on March 6, 1823 He studied law under his father, a Bristol attorney, for two years before taking up medicine He spent five years at the Bristol Medical College and the London Hospital, being, at the time of his death, the oldest living graduate of the latter institution He became a member of the Royal College of Surgeons and the Society of Apothecaries in 1844 In his youth, Dr Fletcher was attracted by American institutions, and, crossing the ocean with his young wife, settled in Cincinnati in 1847 During the Civil War, we find him surgeon of the First Regiment of Ohio Volunteers in 1861, and after three years active service in the field, commissioned as surgeon, U S Volunteers, in charge of Hospital No 7 at Nashville, Tenn., and subsequently medical purveyor of the Army at the same post At the end of the war, he was brevetted lieutenant colonel and colonel, U S Volunteers, for his faithful and meritorious services In 1871, he was on duty in the Provost Marshal's bureau of the War Department active in the preparation of the two volumes of anthropometric statistics issued by that office (1875) and the author of the treatise on anthropometry in the same work In 1876, he became associated with Dr John S Billings in the Library of the Surgeon General's office, and his important labors on its index catalogue extended from the date of publication of its first volume in 1880 to the last year of his life, a period of thirty three years Of the value of this phase of Dr Fletcher's work, it is only necessary to quote the judgment of Dr Billings himself that "the accuracy and typographical excellence of the volumes are largely due to his careful and skilful supervision " The same painstaking care in preparation and proof reading are evidenced in the *Index Medicus*, in the redaction of which Dr Billings and Dr Fletcher were associated as editors for twenty one years (1879 99) and of which Dr Fletcher was editor in chief for nine years, after the journal was revived by the Carnegie Institution in 1903 From his early studies in law, Dr Fletcher acquired a deep interest in medical jurisprudence and was lecturer on this subject at the Columbian University, Washington, D C, 1884 1888, and at the Johns Hopkins University, 1897 1903 He was president of various scientific societies in Washington and the recipient of many honors most prominent of which were the banquet given to him by leading members of the profession on Jan 11, 1906, and the unique award of the gold medal of the Royal College of Surgeons in 1910, a distinction which had been conferred on only eleven physicians in ninety years, most prominent of whom were Parkinson (1822), Thomas Bevill Peacock (1876), Richard Owen (1883), Sir W J Erasmus Wilson (1884), Sir James Paget (1897) and Lord Lister (1897) Only a few days before his death Dr Fletcher was pleased to receive a degree in medicine from the institution which he had first attended in his native town A severe attack of diphtheria in the spring of 1911 brought on a condition of enfeebled health which he bravely weathered but to which he gradually succumbed, dying on the morning of Nov 8, 1912

In personality, Dr Fletcher was a dignified, stately gentleman of the old school, much admired and respected by old and young alike for his cheerful stoicism and military promptitude, his ready wit and courtly ways, and his literary productions were the expression of his personality These are doubly attractive through the simple and direct manner in which the results of exhaustive research are conveyed and a certain strain of grave irony in which, as we have said, he resembles Heberden His earlier essays were entirely in the field of anthropology and include, besides the statistical and anthropometric treatise above referred to, the pioneer monograph in English on "Prehistoric Trephining and Cranial Amulets" (1882), with interesting contributions on Paul Broca (1882), "Human Proportion in Art and Anthropometry" (1883), "Tattooing Among Civilized Peoples" (1883), "Myths of the Robin Redbreast in Earlier English Poetry" (1880), "The New School of Criminal Anthropology" (1891), "Anatomy and Art' (1895), and "Scopelism" (1897), the latter being also the first paper on the subject in English A short paper on "Columns of Infamy" will soon appear in the American Anthropologist (No 4, 1912) Dr Fletcher's affiliations with the Medical Faculty of the Johns Hopkins University led to the production of a number of valuable papers on medical history, of which the best were his essays on "Medical Lore in the Older English Dramatists and Poets" (1895), "The Witches' Pharmacopeia" (1896), and "A Tragedy of the Great Plague at Milan in 1630" (1898) The former of these reveal his unusual offhand knowledge of English poetry, the latter is a remarkable piece of synthetic work, the story having been developed *ab initio* from a rare old Italian engraving An unpublished essay on "Some Diseases Bearing the Names of Saints" will shortly appear in the *Bristol Medico Chirurgical Journal*

The profession will lose in Dr Fletcher the accomplished bibliographer and medical scholar, his intimates will miss the high minded, honorable gentleman, the staunch and loyal friend.

Fielding H Garrison, M D, Washington, D C

The New Hospital at Louisville

To the Editor —I have just returned to Louisville after an absence of ten months spent on the Pacific Coast, and find many changes here in things medical Chief among them is the creation of a million dollar city hospital I once heard it remarked that to judge any place correctly "one should look at the advantage of its public schools and the conditions of its cemetery " These may be good criteria, but I would add, "inspect the hospital intended for the treatment of the poor " Indeed, throughout Europe and this country as well, no greater problem confronts the medical profession than the proper management of these institutions

You will permit, I am sure some detailed mention of the superb building that is now nearing completion in this city It may be that the erection of a similar institution is being contemplated elsewhere in which case those who have charge of the matter may profit by reading this, or what would be better, may accept the invitation to come here and inspect the new building before completing their plans

The hospital occupies a lot 727½ by 342 feet, located nearly in the center of the city This is much to be preferred to a location in the suburbs, owing to the greater ease with which the patient may reach the hospital The plans are on what might be termed a combination of the pavilion and cottage systems The hospital consists of a central administration building, and four ward buildings, arranged symmetrically along a south connecting corridor while the service, clinic and operating building and the psychopathic and special treatment building are on the north side of the corridor Detached from the main group of buildings are the isolation buildings, help building, nurses' home and power plant The buildings are generally of three stories with a high basement The ward buildings have flat roofs with parapet walls, so that they may be used as roof gardens for recreation and outdoor treatments They have elevator service direct to the roof and will prove a valuable adjunct in the modern treatment of disease All the buildings are constructed of concrete, reinforced by steel, and are believed to be fire proof There are no bells used but all signals are given by electric lights communicating directly with the patient's bed Each floor is a separate unit as far as unguarded intercommunication, transmission of noises and cross infection are concerned

The stairs throughout are monolithic, of reinforced concrete faced with terrazzo are absolutely aseptic and are easily cleaned The roof of the administration building has a semi enclosed roof garden, to be used as an outdoor ward for chil dren, so that they may have recreation without disturbing the other patients. It is roofed over and can be open or closed as desired.

One entire floor is taken up by operating rooms and their adjuncts. All specialties have their recognition in a separate and distinct operating room. Amphitheaters have been dispensed with for obvious reasons, excepting that for medical teaching one is provided with a seating capacity of 450; clinical instruction will be given in small rooms provided with skeleton iron stands.

The maternity wards are subdivided, with a ward for waiting women, two rooms for babies, a room for post delivery cases and one for convalescents, with special accommodations for patients who may be infected.

The hospital is provided with psychopathic wards so that suspected persons may be restrained and treated without first being declared insane by a jury.

I desire to call special attention to the fact that one of the most important departments in this hospital is that of nursing and a special nurses' home has been provided. This is the more important, as the training school is maintained here. It is a maxim that has been proved true, that the better a hospital cares for its nurses, the better will be the class of women who enter the training school. Each nurse is provided with a separate room, plainly, neatly and tastefully furnished, each with clothes closet, lavatory with hot and cold water, a small *combined desk and a wall bookcase. A small infirmary is* built for those who may be ill. Special rooms afford opportunities for nurses to entertain their friends, and small kitchens have been built where nurses may prepare little treats for themselves or their friends.

It would take pages to describe in detail this splendid hospital, but I will make this suffice. I believe that it is the most modern and up to date hospital in the United States. It was erected under the supervision of a non partisan commission on which was a physician, Dr. Ap Morgan Vance. Without disparagement to any one of the other distinguished and honored members of the commission, it can truthfully be said that much of the success in this great enterprise is due to Dr. Vance, who has been untiring in his work. Together with the others, Louisville owes him a deep debt of gratitude, and the medical profession here is proud of him and his work as evidenced in the result.

Joseph M. Mathews, Louisville, Ky.

Queries and Minor Notes

Anonymous Communications will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

AVOIDANCE OF NERVOUS SHOCK IN ANESTHESIA

To the Editor:—1. Some time ago I saw in a lay paper the statement that from Paris had come a feature in surgical procedures that would rob operations of all their horrors: the hypodermic (or intramuscular?) injection of ethyl chlorid a day or two before operation to paralyze the fear center in the brain. Please send me some details or refer me to some articles regarding it. That with persistence of local anesthesia for days after injection of urea hydrochlorid and quinin would be very desirable.

2. Please tell me how reliable the Noguchi modification of the Wassermann test is.
J. I. R.

Answer.—1. The newspaper report referred to by our correspondent is probably the result of a play of popular fancy on a meager scientific basis. In our Paris Letter (The Journal, May 25, 1912, p. 1612), intramuscular etherization is mentioned. Dr. Descarpentries occasionally used an inhalation of ethyl chlorid preliminary to the intramuscular injection of the ether. This method of intramuscular etherization has been condemned by a number of Paris physicians, as will be seen in The Journal of July 27, 1912, p. 288. Considering the extreme volatility of ethyl chlorid, one would hesitate to use it by hypodermic injection.

The aim of the procedure suggested seems to be the same as that of Crile's principle of *anoci association*. According to this the effort is made to plan and carry out operations so as to prevent the formation of harmful associations and the discharge of nervous energy leading to exhaustion. This is done by avoidance of everything that may tend to cause the patient preliminary worry or fear, and by cutting off the brain from the operative area by local anesthesia in addition to general anesthesia during operation, and by local anesthesia alone for a considerable period after operation. See Crile: The Results of Operations, Especially Abdominal, Performed on the Principle of Anoci Association, The Journal, July 13, 1912, p. 114. Watson's modification of Crile's procedure (*Med. Rec.*, Oct. 5, 1912, p. 617) is to put the patient under local anesthesia before beginning general anesthesia and to begin and finish the operation under local anesthesia alone.

2. Many observers believe that the Noguchi modification is as reliable as the original Wassermann method, and others consider it more reliable.

QUALIFICATIONS FOR PRACTICE IN WEST VIRGINIA

To the Editor:—Can an unregistered physician legally practice medicine in West Virginia as the hired assistant of a qualified and registered practitioner? In answering please omit my name.
H. J. S.

Answer.—No person can practice medicine legally in West Virginia unless he holds a certificate issued by the State Board of Health. Section 4390 of Chapter 150 of the Code of West Virginia is as follows: "The following persons and no others shall hereafter be permitted to practice medicine in this state: 1. All such persons as shall be legally entitled to practice medicine in this state at the time of the passage of this act. 2. All such persons as shall be graduates of a reputable medical college *recognized as such by the State Board of Health*, who shall pass an examination before said State Board of Health and shall receive certificates therefrom, as hereinafter provided."

THYMUS SUBSTANCE IN ARTHRITIS DEFORMANS

To the Editor:—Please refer me to any articles on the treatment of arthritis deformans with thymus gland. I read an article on the subject which appeared in The Journal but am unable to find it again.
C. T. Lankhurst, North Star, Mich.

Answer.—References to articles on the treatment of arthritis deformans with thymus substance were given in this department Sept. 28, 1912, p. 1205.

FINLAY'S MOSQUITO THEORY OF THE TRANSMISSION OF YELLOW FEVER

To the Editor:—In your interesting answer (November 9, page 1713) to the question of Dr. I. J. McKinley concerning the relation of the mosquito to disease, you make no mention of Dr. Finlay of Havana, for whom some claim priority in the suggestion that the spread of yellow fever is due to the mosquito. I am sure that it will interest many of your readers to have the facts of this relation presented.
James Tyson, Philadelphia.

Answer.—To Dr. Carlos J. Finlay of Havana is generally awarded the credit for first explicitly pointing out the connection between *the carrier and the disease. In 1881 Finlay* advanced the theory of the conveyance of yellow fever by the bite of the mosquito and correctly distinguished the species of mosquito (*Stegomyia calopus*) which, as later proved by the experiments of the American Yellow Fever Commission, transmits the disease to man. He had not at that time the advantage derived by later investigators from knowledge of the rôle played by the mosquito in malarial fever and believed yellow fever to be conveyed from one patient to another by direct inoculation of a virus. While his experiments undertaken to prove the theory were uniformly unsuccessful, this detracts nothing from the value of the inductive reasoning by which he reached his conclusion. The dramatic interest attaching to the heroic work of the U. S. Army Yellow Fever Commission has tended to overshadow Dr. Finlay's work somewhat in popular estimation, but members of the commission in their published writings have acknowledged that they were working on the foundation supplied by Dr. Finlay's theory. No discovery in early literature of any casual hint or hasty hypothesis as to the relation of mosquitoes to yellow fever will disturb Finlay's claim to credit as the man who for twenty years pertinaciously defended the theory [illegible] in the face of an indifferent if not hostile public. [illegible] in this [illegible] as in many others it is interesting to [illegible] how correct the [illegible] and suggestive observation [illegible] the [illegible] who conceived the theory [illegible] *failed to appreciate their value* [illegible] time or opportunity to follow them up. [illegible] inappropriate to [illegible] with [illegible] claims to recognition as those discussed November 9 the solid and undisputed facts as to Finlay's connection with the subject Perhaps this was a mistake, at all events the neglect to mention Finlay was not prompted by a desire to depreciate his achievement

IS LIGHT FATAL TO PLASMODIA?

To the Editor —In The Journal, October 12 p 1381 you write on Cultivation of Malarial Plasmodia and refer to an action of quinin

The rediscovery of the filaria by observers in Egypt following its discovery by ——————' was put off by the neglect to examine the patients after sunset the parasite coming to the surface of the body in the dark Negroes native to Africa become immune to malaria (and filariasis) by having skins impervious to light The three substances causing death of the plasmodia are all substances which have the power of causing fluorescence They are quinin, esculin and fraxinin

Is it not likely from these facts that light or actinism is fatal to plasmodia and that exposure of patients to sunlight after introducing one of the above named fluorescent substances would hasten recovery? Edmund D Spear M D *Boston*

Answer —The theory that the action of quinin on malarial parasites is connected with its property of fluorescence was advanced a number of years ago While it is a curious circumstance that the substances enumerated by our correspondent are fluorescent, we do not think that the theory that fluorescence is necessary to a pharmacologic action is rational

It is a remarkable fact that quinin exhibits fluorescence only when the haloid acids or salts are not present Such salts as chlorids, bromids or iodids added to a fluorescent solution of quinin prevent the occurrence of fluorescence Since the blood contains chlorids in a considerable quantity, it is not reasonable to expect the fluorescence of quinin to be exhibited in such a medium, and hence it would seem improbable that this property could affect the action of the remedy on the plasmodia. Moreover, certain cinchona alkaloids, such as cinchonin or cinchonidin are not fluorescent, but have a positive action on malaria

NO SODIUM SALICYLATE HYPODERMIC TABLETS—NO ARTIFICIAL QUININ

To the Editor —1 Why are not hypodermic tablets of sodium salicylate or any other salicylate preparation on the market for hypodermic use?

2 Is the quinin in common use natural or artificial and if the latter does it possess the same antimalarial virtue as that derived from natural sources? Ralph S Cone, M D Westwood N J

Answer.—1 Sodium salicylate is not used for hypodermic injection because the dose is large, and, unless much diluted, would be likely to cause irritation Usually this substance can be given by the mouth without inconvenience, and it has been proposed, in cases in which the stomach is rebellious, to administer it by rectal injection We do not know that any proposal has been made to administer it hypodermically It is not put up in the form of hypodermic tablets by the pharmaceutical houses because there is no demand.

2 So far as we know, no artificial quinin has been put on the market The quinin in commerce is obtained from the compounds of quinin existing in cinchona bark

OINTMENT FOR CARCINOMA OF THE SKIN TREATMENT FOR ALCOHOLISM

To the Editor —1 Please publish the formulas of the ointment used to remove moles and carcinoma of the skin that you published several months ago It was similar to the remedy Squibb & Sons sold.

2 Also refer to the page that contained the treatment for alcoholic patients Ross C Martin M D Kokomo Ind

Answer —1 The ointment to which our correspondent refers is probably the proprietary Thoremedin formerly called Thoradin, of which we published an analysis, March 9, 1912, p 719

2 The article entitled "The Treatment of Drug Addiction," by A Lambert, was published in The Journal Feb 18, 1911, p 503

CONTINUED USE OF SODA IN HYPERCHLORHYDRIA

To the Editor —Please answer the following in your Queries and Minor Notes Department, and do not publish my name Can the continued use of sodium bicarbonate in 30 grain doses taken after each meal say for a term of years for hyperchlorhydria do any harm? Could it be a possible factor in producing general pruritus? M. T R

Answer —The dose mentioned will barely neutralize the acid in 500 c.c of normal gastric juice In case of hyperacidity it would not completely neutralize the acid In case the alkali is completely neutralized by the acid in the gastric juice, as would probably be the case in presence of hyperacidity, sodium chlorid would be formed, so that the use of the sodium bicarbonate would be practically equivalent to the administration of a small dose of about 20 grains of sodium chlorid Of course, it is not advisable to continue a single remedy for so long a time, and certainly it would be desirable to make frequent examinations of the stomach contents to determine that the hyperchlorhydria continues The effect of the continued neutralization of the stomach contents might be to cause a frequent or continual alkalinity of the urine, which might have undesirable results In general, however, the use of alkalies in hyperchlorhydria is productive of good and not harm

BISMUTH PASTE

To the Editor —Please publish formulas for bismuth paste as used by Beck and others J M F

Answer.—The following were recommended by Beck in his original article in The Journal, March 14, 1908, p 868

Formula of paste for diagnosis and early treatment

℞

Bismuth subnitrate	1 part
Petrolatum	2 parts

Mix while boiling

Formula of paste for late treatment

℞

		gm		
Bismuth subnitrate		30		℥i
White wax				
Soft paraffin	āā	5	āā	gr 75
Petrolatum		60		℥ii

Mix while boiling

Another formula was given in Dr McKelvey Bell's article, The Journal, May 4, 1912, p 1340

℞

Bismuth subnitrate	1 part
White petrolatum	2 parts

Dissolve on hot water bath stirring until cool then (still stirring) add 5 per cent of iodoform (i e 72 gr)

OXYPATHOR

To the Editor —Can you give me any literature on the Oxypathor? There is a woman pushing it in Harrisburg She has a sign on her door and travels from house to house trying to sell it for $35 One is on exhibition in a book store window It is a fake They have sold a number claiming that it cures all diseases David J Hetrick, M D Harrisburg Pa.

Answer —Our correspondent is right The Oxypathor is a fake and one of the most impudent on the market. It used to be sold under the name "Oxygenator" and as such has been debarred by the Australian government from importation into that country, also, its sale was prohibited some time ago in the state of Vermont The device is essentially a nickel plated piece of gas pipe filled with a crude mixture of inert substances, apparently iron filings, clay and coke dust This fraud is exposed at some length in a pamphlet issued by the American Medical Association entitled "The Oxydonor and Similar Fakes," which will be sent on receipt of four cents in stamps The same matter appears in the book "Nostrums and Quackery," price one dollar

LITERATURE ON POSTGRADUATE WORK ABROAD

To the Editor —Have you any bureau of information or literature which will give me valuable and necessary information for reaching and profiting by a course of study in the medical schools of Europe particularly the schools in Berlin?

E Hornibrook M D Cherokee, Iowa

Answer —Our correspondent and a number of others who have made similar inquiries are referred to this department of The Journal, Oct 5, 1912, p 1310, Oct 19, 1912, p 1474, and April 8, 1911, p 1050 The last reference is to a long article describing the facilities of the chief medical centers of Europe in detail

SEXUAL DESIRE AFTER CASTRATION AFTER PUBERTY

To the Editor —Please inform me if castration after puberty completely or only partially destroys the sexual desire and also if a double oophorectomy completely destroys or only partially inhibits the sexual desire in the female P T R

Answer.—It is usually believed that castration after puberty may permit the retention of a certain amount of sexual desire This is certainly true in the case of double oophorectomy In the latter case some women lose their sexual feeling, while others retain it apparently unimpaired

CONVERSE TREATMENT FOR EPILEPSY

To the Editor —Please tell me the composition of the Converse Treatment for Epilepsy

S I L

ANSWER —Practically every nostrum on the market sold for the self treatment of epilepsy contains large quantities of bromids These are taken by the patient in utter ignorance of the danger and in quantities that no physician with any respect for his patient's safety or his own good name would dare prescribe Such heavy doses suppress the attacks but brutalize the patient and lead to a loss of mental and physical activity The Converse Treatment for Epilepsy was analyzed by Prof E F Ladd of the North Dakota Agricultural Experiment Station Professor Ladd reported that the sample was an aqueous solution of several bromids with an aromatic galenical preparation, and that it contained

Ammonium bromid	4 28 per cent
Total bromin	10 306 per cent

Professor Ladd added "The total bromin calculated as the equivalent of potassium bromid would equal 15 486 per cent But not all of the bromin is in combination with the potassium, for there are present in the preparation sodium bromid potassium bromid, strontium bromid, ammonium bromid and iron bromid "

Affiliation of Hospital with Medical School

The announcement has recently been made of an affiliation between the New York Hospital and the Medical Department of Cornell University in New York City The terms of the copartnership are that in consideration of a substantial fund donated to the hospital to aid its future building projects, the institution gives to the medical college for purposes of teaching and research one half of its entire service, comprising medical, surgical and children s wards in all about 150 beds The exact amount of the gift has not been made public, but the donor, Mr George F Baker, is a member of the board of governors of the New York Hospital and is said to be deeply interested in medical education He thus evinces his conviction that the greatest efficiency for both hospital and medical school is to be attained through coalition This coalition is fully in accord with the principles long advocated by the Council on Medical Education of the American Medical Association Already throughout the country fully a dozen coalitions between university medical schools and neighboring hospitals have been brought about Each coalition strengthens the cause of higher medical education by increasing the opportunities of colleges in both undergraduate and graduate instruction and by supplying them with the definite field for advanced research without which such work must always be restricted The further announcement is made of the gift to the medical college by another philanthropist of a $1 000 annual fellowship in medicine to be allotted for work in the New York Hospital medical wards The college besides large building properties and equipment now possesses an endowment for maintenance of $4 000 000 which places it among the highest endowed medical schools in the country

Georgia October Report

Dr C T Nolan secretary of the Regular Medical Examining Board of the State of Georgia reports the written examination held at Atlanta Oct 8 10 1912 The number of subjects examined in was 10 total number of questions asked 100, percentage required to pass 80 The total number of candidates examined was 30 of whom 20 passed and 10 failed The following colleges were represented

PASSED College	Year Grad	Per Cent
Birmingham Medical College (1911) 87 5	(1912) 80	80

Book Notices

Life and Letters of Dr William Beaumont Including Hitherto Unpublished Data Concerning the Case of Alexis St Martin By Jesse S Myer A B M D Associate in Medicine in Washington University, St Louis With an Introduction by Sir William Osler Bt M D F R S, Regius Professor of Medicine in Oxford University, England Cloth Price $4 Pp 317 with illustrations St Louis C V Mosby Company 1912

William Beaumont, the first great American physiologist, was licensed to practice physic and surgery by the Third Medical Society of Vermont in 1812 He had then studied medicine for two years with Dr Benjamin Chandler in St Albans One hundred years later, and fifty nine years after his death in St Louis, appears this complete story of his life and work In the words of Sir William Osler, three generations have now been interested in the work of Beaumont as well as in 'that fistulous Alexis" who was the, at times, elusive subject of his remarkable experiments The chief facts of the life of Beaumont have become well known from the many addresses and sketches that have been printed about him and his work but authentic sources for an adequate biography became available only recently when a wealth of family papers records manuscripts and letters were placed at the disposal of Dr Myer, who has spared no pains in collating this vast material to the best advantage and in following every promising thread of information to its end New England town records the surgeon general s office in Washington, various army posts, the scenes of Beaumont's activities, old newspapers and letters have been ransacked for information Every page is a witness of labor of love on the part of Dr Myer to give us a faithful picture of the great Beaumont in its proper setting so that we are able, "as it were, to see him alive" The illustrations and fac simile reproductions of letters, documents and old newspaper notices are most interesting Beaumont's letters and other writings reproduced unaltered in the various chapters serve to keep safe his individuality The result is a book that it is a real pleasure to welcome, for it constitutes a contribution of the first importance not only to the history of medicine in America but to the history of physiology It will take its place among the classics in medical biography and merits the widest distribution possible

The Pituitary Body and Its Disorders Clinical States Produced by Disorders of the Hypophysis Cerebri An Amplification of the Harvey Lecture for December 1910 By Harvey Cushing M D Associate Professor of Surgery the Johns Hopkins University Cloth Price $4 Pp 341 with 319 illustrations Philadelphia J B Lippincott Company, 1912

The anxiously expected monograph on the hypophysis has at last made its appearance Those who have followed the author's labors in this new field expected an authoritative work from his pen This monograph more than justifies expectations The subject matter is largely drawn from an enormous personal experience with the clinical and surgical affections resulting from hypophyseal disorders, supplemented by experiments on animals The theoretical views advanced are in keeping with the latest thought The case reports are well worth studying for their intrinsic merits, they are concise and yet complete and indicate the author's participation, rather than the transcribing of an ordinary hospital record The text is profusely illustrated with excellent reproductions from photographs of patients, and the microphotographs and radiographic pictures are exceptionally fine As this book is the outgrowth of the Harvey lecture for *1910*, its style in places is quite literary in character, but if anything this is a merit rather than a fault in a monograph dealing with so many new facts Every line mirrors the author, being peculiarly cushingian in its positiveness In his systematic summary of the entire subject Cushing gives due credit to every worker in this new field and his bibliography includes 256 references While many of the views expressed will undoubtedly need modification as soon as new experiences accumulate, at the present time this monograph reflects the most modern and mature thought on the hypophyseal disorders

Collected Papers by the Staff of St Mary's Hospital Mayo Clinic Rochester Minn 1911 Cloth Price $5 50 net Pp 603 with 250 illustrations Philadelphia W B Saunders Company 1912.

This volume includes the papers of the Mayo Clinic for 1911 and naturally a large variety of subjects is considered. The greater part of the book is devoted to the alimentary canal and the genito urinary organs Ductless glands receive a comparatively small share of attention Of special interest is the group of papers on diagnostic aids, including radiographic diagnosis and the use of the cystoscope The paper by Dr J H Selby, on "Collaboration in Radiographic Diagnosis," is profusely illustrated The papers on the ductless glands are by Dr Charles H Mayo, with one on "Parathyroids and Their Surgical Relations to Goiter" by Drs Charles H. Mayo and Bernard F McGrath The book closes with an obituary of William Worrell Mayo, the father of the Mayo brothers, who died March 6, 1911, at the age of 92

Lectures on General Anesthetics in Dentistry Advocating Painless Dental Operations by the Use of Nitrous Oxid Nitrous Oxid and Oxygen Chloroform Ether Ethyl Chlorid and Somnoform By William Harper DeFord A M D D S., M D Dean and Professor of Oral Pathology and Anesthetics Drake University College of Dentistry Cloth Price $2 50 Pp 312, with illustrations Pittsburgh Lee S Smith & Son Company 1912

Many new appliances for the safe administration of anesthetics have been introduced to the profession during the past year The second edition of this most valuable work is made necessary to bring the account of these later inventions up to date The first chapter is devoted to the subject "Has the Dental Surgeon the Right to Administer General Anesthetics?"

After discussing the merits of general anesthetics the author concludes that the dentist has the right to administer them if he possesses the requisite knowledge, skill and experience On the other hand, he has not the right to administer anesthetics unless he is familiar with their effects and can show his proficiency in this respect The author then discusses the value of general anesthetics in dental operations He shows the necessity of reducing pain to the minimum in the different operations, such as preparing cavities and extracting teeth The subject of shock in preparing cavities of the teeth and a general discussion of anesthetics follow

Pathologie des Herzens Von A Vogt o Professor der allgemeinen Pathologie an der kaiserlichen Universität Moskau Autorisierte Uebersetzung aus dem Russischen von Dr Julius Schütz. Paper Price 8 marks Pp 168 with 20 illustrations. Berlin Julius Springer 1912

This monograph presents in clear, concise and readable form the essential facts of cardiac pathology, the subject being approached from the side of pathology rather than from that of the clinical manifestations, diagnosis or treatment Cardiac diseases, as a rule, are clearly traced to anatomic lesions, and the proper emphasis is laid on the resulting disturbance of function The subject is presented in the form of eight lectures Facts are clearly distinguished from theory, animal experiment is often adduced in support of the views advanced and a knowledge of the clinical manifestation of heart disease is evident The author shows familiarity with the literature There is a lack of discussion of some of the more recent work on the heart, which omission is frankly stated in the preface An extensive bibliography is found at the end of the work

The Practitioner's Visiting List for 1913 Leather Price $1 25 Pp 192 Philadelphia Lea & Febiger 1912

Among the useful data in this visiting list are periods of dentition, weights and measures comparative scales examination of the urine, important incompatibles, poisons and antidotes, table of doses and therapeutic reminders The best hint given, however, is in the first line "Keep your visiting list in such a way that you can fully explain it" This sentence alone is worth the price of the book, because physicians are sometimes haled into court because of a dispute about the bill for services rendered, and at such a time an 'explainable" visiting list has often been the means of securing a decision in the doctor's favor This book is of convenient size well bound in red leather, and printed on good strong paper Provision is made for keeping a record of visits, vaccinations, confinements, addresses and a cash account

The Cheerfulness of Death By W W Keen M D LL.D Paper Price $0 15 Philadelphia The Griffith and Rowland Press 1912

This neat pamphlet contains, besides helpful extracts from Holmes, Tennyson and Newman words of Christian encouragement concerning the crossing of the bar and the life beyond It is well designed to minimize the apprehension which a patient may have on considering the approach of death

Medicolegal

Operating Without Consent of Patient—Common Law Rule Must Be Adapted to the Employment of Anesthesia in Surgical Operations—Surgeon is Patient's Representative

(Bennan vs Parsonnet (N J) 83 Atl R 948)

The Supreme Court of New Jersey holds that a verdict for $1,000 damages for alleged malpractice cannot be permitted to stand being against the clear weight of evidence It says that the plaintiff applied to the defendant to operate on a rupture in his left groin that had been unsuccessfully operated on two years before by another surgeon On learning that the plaintiff was a poor man the defendant engaged to operate free of charge At the time fixed for the operation the plaintiff was placed under the anesthetic by two assisting surgeons who, when the defendant came into the operating room, directed his attention to a rupture they had just discovered in the patient's right groin which on examination and the employment of the usual diagnostic tests was determined by the three surgeons to be a serious menace to the patient and likely to cause his death should strangulation occur, dangers not to be apprehended from the rupture that had once been operated on The defendant thereupon operated on the more serious rupture intending to operate also on the other which he was prevented from doing by the patient's condition under the anesthetic The patient on being informed that the operation would be completed on a following day, apparently acquiesced but later declined to go on with the operation and brought this action against the defendant for assault and battery

The trial judge charged the jury that the operation was a legal wrong to the plaintiff unless he had consented to its performance explaining to them that such consent as to conditions discovered after the operation had actually commenced might be inferred from circumstances, and that it should be inferred if the condition thus discovered endangered the life or health of the patient leaving to them the question whether the condition for which the defendant had operated was of that character On the question thus submitted to the jury the evidence was overwhelming against the verdict The testimony of unimpeached medical witnesses that the rupture that was operated on was a serious menace to the health of the plaintiff and even to his life should it become strangulated was not even attempted to be contradicted On this point the testimony of the witnesses who had personal knowledge of the facts, was corroborated by that of a witness who was shown to be a surgeon of great experience and a recognized authority in his profession A verdict rendered in the face of this testimony could rest only on the assumption of superior knowledge by the jury The duty of the jury was to render a verdict on the evidence and that it did not do

The verdict must therefore be set aside without regard to whether the question that was left to the jury was or was not the precise question that should have been submitted to them although the court thinks that it was not It is true that the judge in his charge laid down the common law rule with substantial correctness but it is also true that the introduction of anesthesia into the practice of surgery has modified the application of the common law rule in certain fundamental respects of which the law must take notice The trial judge in his charge followed the opinion of Judge Brown in Mohr vs Williams, decided by the Supreme Court of Minnesota 95 Minn 261 which as annotated in 1 L R A (N S) 439 correctly presents the common law rule on the subject That rule is thus stated in 1 Kinkead on Torts p 395 "The patient must be the final arbiter as to whether he shall take his chances with the operation or take his chances of living without it Such is the natural right of the individual which the law recognizes as a legal one Consent therefore of an individual must be either expressly or impliedly given before a surgeon may have the right to operate In general justification of this common law rule, Judge Brown says in his opinion "There is logic in the principle thus stated for in all other trades professions or occupations contracts are entered into by the mutual agreement of the interested parties and are required to be performed in accordance with their letter and spirit No reason occurs to us why the same rule should not apply between physician and patient"

Without stopping to point out the fallaciousness of the premise that a surgical operation can be contracted for or performed according to plans and specifications it is enough to say that the entire foundation of the supposed analogy is swept away by the surgical employment of anesthesia which renders the patient unable to consent at the very time that the rule of the common law required that his consent be obtained for in those days the patient (such was the law of it) was a conscious participant in such surgical operations as were then performed and as his consent [illegible] the rule of the common law was [illegible] The surgical employment of [illegible] common knowledge not only [illegible] ing the patient's consent during the operation, but has also had other radical effects of which notice must be taken Thus it has rendered possible and of everyday occurrence surgical operations of a character and magnitude not dreamed of at the time the common law was in the making, and, as a matter of practical moment, has also advanced the period that marks the commencement of a surgical operation from the time when the patient's body is actually invaded by the knife to the time when the anesthetic is administered, or at least when the patient has succumbed to its influence The employment of anesthesia has also postponed to this same period of relaxation and unconsciousness the making of that complete and final diagnosis of the patient's condition that at common law was made at a time when he could be both informed and consulted By these considerations the scope of modern surgical operations has been greatly enlarged, and the legal rule applicable thereto extended beyond the emergencies of actual surgery to other matters more or less vitally affecting the patient's welfare To meet these changed conditions, the rule of law must, in the interest alike of the patient and the surgeon, be adapted to the changes that have been so wrought, chief among which is the unconscious state of the patient at a time when by the common law rule his consent must be obtained To meet this fundamental change in the condition of the patient, it is imperative that the law shall in his interest raise up some one to act for him—in a word, to represent him in those matters affecting his welfare concerning which he cannot act for himself because of a condition that has become an essential part of the operation

If such a representative has been chosen by the patient himself, the rule we are considering has no application, but, if no one has been so appointed, the law by its constructive power will raise up such a representative without which the welfare and even the life of the patient might be needlessly sacrificed To meet the requirements of the case, such representative should not only keenly appreciate the nature of the duty that is thus cast on him, but also be possessed of the knowledge and skill to perform such duty with wisdom and promptness He should also be one in whom the patient reposes confidence and on whose judgment he would presumably rely The surgeon whom the patient himself has selected alone fills all of these requirements, and hence on him the law would cast the responsibilities of this office by the legal implication that the patient intended him to act for him when he had made no other selection

This implication accords with those analogies of the common law by which prompt and timely aid to accidentally injured or unconscious persons is secured from those not expressly authorized to render it And I (the court's opinion was prepared by Justice Garrison) have no doubt that, should such an accident occasion a depression of the skull that rendered the injured person unconscious, the consent of such person to the necessary surgical operation would be implied at common law, although I find no such reported case A like analogy to some extent is found in the American decisions touching actions for compensation for services rendered to unconscious persons a topic on which the English cases are silent owing to that hallucinatory honorarium on which the learned professions in Great Britain are supposed to rely for their subsistence At bottom these analogies all rest on the maxim that one is presumed to accept that which is beneficial to him, a doctrine that, if applied to commerce and the transfer of property, should surely be applied where life and health are at stake

The conclusion, therefore, to which the court is led is that when a person has selected a surgeon to operate on him, and has appointed no other person to represent him during the period of unconsciousness that constitutes a part of such operation, the law will by implication constitute such surgeon the representative pro hac vice (for this disability) of his patient, and will, within the scope to which such implication applies, cast on him the responsibility of so acting in the interest of his patient that the latter shall receive the full benefit of that professional judgment and skill to which he is legally entitled. Such implication affords no license to the surgeon to operate on a patient against his will or by subterfuge, or to perform on him any operation of a sort different from that to which he had consented or that involved risks and results of a kind not contemplated As to such matters, the rule in question submits nothing to the judgment of the surgeon, who as the implied representative of his patient can under such implication truly represent him only in so far as he gives to him the benefit of his professional wisdom within the general lines of the curative treatment agreed on between them, unless, of course, a wider discretion has been accorded to him Within such general lines, however, much is necessarily left to the good judgment of the operating surgeon, just how much will depend on the circumstances of the individual case

If the surgeon transcends his implied authority as thus defined, the question of his skill and wisdom is irrelevant, since no amount of professional skill can justify the substitution of the will of the surgeon for that of his patient, but where this is not the case, and where the act done or the decision made in the interest of the patient is fairly within the implied duty and authority of the surgeon, the question for the jury is whether on the evidence it appears that such professional skill and wisdom as the patient was entitled to receive had been exercised by the surgeon in his behalf, not whether in the opinion of the jury the surgeon had acted wisely or whether the patient had been benefited

Such being the question for the jury, the admissibility of the technical or expert evidence on which it rests presents, as in other cases of relevancy, a preliminary question for the court which in the present case the trial judge rightly resolved in favor of the admission of such evidence. A ruling that the operation that was performed by the defendant was of a different sort from that to which the patient had consented would be based on too narrow a view The condition for the cure of which the plaintiff applied to the defendant was rupture He was therefore presumed to have contemplated all of the risks incident to an operation for such a condition Now rupture is simply a protrusion of the intestine. Whether it occurs on the right side or on the left the intestine is the same, the muscular wall is the same, and the operation is the same, and its dangers and the risks are the same

The real question is one to be settled, not by authority, but by reason, and its importance is such that it touches at a vital point the interests of the entire public, any member of which may at any time suffer in life or health by the establishment of a rule that will paralyze the judgment of the surgeon and require him to withhold his skill and wisdom at the very juncture when they are most needed, and when, could the patient have been consulted, he would manifestly have insisted on their being exercised in his behalf This concluding suggestion may perhaps be ethical rather than legal, but it does seem that in good morals a patient ought not, in his efforts to obtain a money verdict, to be permitted to repudiate the sound judgment exercised in his behalf by the surgeon of his choice, in whose judgment he would unquestionably have concurred

MEDICAL SOCIETY OF VIRGINIA

Forty Third Annual Meeting held in Norfolk Va Oct 22 25 1912

The list of officers elected for next year was given in The Journal, November 2, page 1636

Gastric and Duodenal Ulcer

Dr J S Davis, Charlottesville In one case of supposed stomach ulcer, with pain felt directly on swallowing, a prune seed was found imbedded in the lower esophagus Males predominate among gastric ulcer patients, text books to the contrary notwithstanding Hasty eating and worry predispose, and this makes doctors specially liable In one case the odor of hydrogen sulphid was present and the colon bacillus was found. Of forty five cases seen at the University of Virginia, twenty five were gastric, only three occurred in colored persons, two of whom were bright mulatto, the ages were from 18 to 65 The impregnation test is of some value, in this test the patient swallows the end of a thread and retains it in the stomach all night, then it is withdrawn and examined for blood, bile, etc Roentgen ray examination will show deflection of the peristaltic wave at the ulcer

Medical Treatment of Gastric and Duodenal Ulcer

Dr J G Nelson, Richmond Little that is new has been added in the last year or two Why should not incisions and needle wounds become ulcers? They do not There is the same neuropathic condition, the same neuritis or definite microbic invasion A local diminished resistance is now accepted as the most tenable theory A large percentage of patients recover if properly handled. Acute non perforating ulcer should be exempt from incision Practically rest, regulation of the diet, bismuth and epinephrin make up most of the treatment and of these rest is the most important The stomach wall must be kept still. Rectal feeding may be used, no long tube is required, but injection should be made slowly, at six hour intervals Concentrated solutions of sugar are irritating, but cane sugar less so than grape sugar Bismuth subcarbonate may be given in doses of from 300 to 400 grains, no constipating effect need be feared or chalk, 1 dram in a little water, may be given Treatment should be long enough, and the patient kept under observation a year or more For hemorrhage, morphin is the best agent

Surgical Treatment of Gastric and Duodenal Ulcer

Dr. Lomax Gwathmey, Norfolk Bear in mind the possibility of acute perforation, and obtain prompt surgical consultation if this occurs Acute hemorrhage is not always an indication for surgical treatment. Immediate gastrojejunostomy will control Repeated hemorrhage demands operation Experience makes me advocate early operation It is important to recognize symptoms, and not to give cathartics or morphin, masking the symptoms for the surgical consultant Right rectus incision gives the best results, and speed spells success Look for multiple ulcers

Pyloric Ulcer Secondary to Appendicitis, Colitis and Other Foci of Infection Within the Portal Area

Dr G Paul LaRoque, Richmond Bacterial cultures are invariably positive in tissues taken from chronic gastric ulcer Chronic appendicitis presents striking similarities, and also differences As to ages, the average for appendicitis is 25 years, for pyloric ulcer 34, for biliary calculi 39, for duodenal ulcer 45, and for gastric ulcer 48 Acute ulcer can be produced by experimental infection The first part of the duodenum soon will not be called duodenum at all, but part of the stomach It has no valvulae conniventes Pyloric ulcer is probably always primary

DISCUSSION

Dr W P Carr, Washington, D C Slowing of food in the stomach, shown by skiagram may be due to anatomic stricture or spasm of the pylorus, when the latter on operation no apparent change is seen in the pylorus It is produced by irritating substances in the stomach acting either at long intervals or constantly In all chronic ulcers there is some form of obstruction Patients may recover from acute ulcers but they nearly always recur The chronic ulcer is always surgical from the beginning The coincidence of appendicitis gall bladder infections etc with stomach ulcer does not show appendicitis, etc to be the cause, but vice versa Infection travels downward not upward

Dr J S Horsley Richmond One point I wish to emphasize is that chronic indigestion, unrelieved by medicines in about six or eight months is a surgical condition

Dr P S Roy Washington D C In differential diagnosis the hemoglobin index plays an important part I recently had a patient a neurotic girl of 22, with hematemesis, who had been treated by a distinguished Boston man I found that this bore relation to menstrual periods I treated only the nervous condition and the patient seems to have recovered entirely I do not think it common for cancer to start on ulcer

Dr I S Stone Washington, D C We see these associated lesions constantly in cases in which we operate such as fibroid tumors etc., when no suspicion of stomach ulcer exists

Dr. George Tully Vaughan, Washington, D C If symptoms are evident submit the case to medical treatment for six or eight weeks, if no relief follows then call in a surgeon It is a mystery why surgeons hesitate to operate in acute hemorrhage In nearly all other forms of acute hemorrhage they operate right away The obvious thing to do is to stop the hemorrhage in gastric ulcer as in typhoid perforation All agree as to the propriety of operating in chronic cases Pylorectomy is the ideal operation for this condition Take out the pylorus if your patient can stand it

Dr Kirkland Ruffin, Norfolk The important thing to decide is whether the digestive disturbance comes from conditions in the abdomen or other general conditions I operated in two cases of gastric disturbance in pellagra, the skin symptoms being dormant

Old and Modern Theories of Fetal Development, with Report of a Case of Boy with Three Legs

Dr Stuart McGuire Richmond This child was born with three legs of equal length, the third leg being attached to the pubes just above the penis The mother was satisfied that it was the result of maternal impression She was advised to wait till the child was 2 or 3 years old and then have it removed Nothing further was heard of the case until last summer when the youth was brought to me, 13 years old The leg had been carried doubled on the abdomen and held by a bandage There was no patella, and the foot had nine toes The leg was removed and the boy made a perfect recovery

Protection and Repair of the Perineum

Dr Greer Baughman, Richmond I deliver with the patient in the lithotomy position until the head is about to be expelled Then I bathe the vulva and thighs in sterile solutions, compound solution of cresol, etc give an anesthetic to the obstetric degree have the nurse extend the legs and evert the feet bringing the thighs as close together as possible with the heels in and the toes out, and I gather up the fasciæ and try to deliver between pains In delivering the shoulders I have to have more room so I separate the thighs a little The advantage of extending the thighs is that the skin from the buttocks is put at the disposal of the perineum The method was suggested by Dr Charles Robins If tear occurs I repair at once, using separate catgut suture for each tear, if the rectum is torn silkworm gut suture may be used

Indications for Cesarean Section

Dr. Virginius Harrison Richmond Placenta praevia eclampsia contracted pelvis tumors and cancer of the cervix vagina or rectum are the indications for the operation The vaginal route is not indicated in many cases in my opinion even if the child lives you generally have a badly torn perineum and the other way you have a clean wound to heal The vaginal route seems to be the choice of most operators in eclamptic cases Physical incapacity of a small uterus may be put down as a sixth indication Inaction is the worst possible policy in eclamptic cases

DISCUSSION

Dr R L Payne Norfolk Mortality statistics on placenta praevia are unreliable Repeated tamponade and repeated examinations are liable to infect The proper treatment of placenta praevia begins when the hemorrhage begins and admits of no delay We have no right to jeopardize the life of the mother while waiting for the viability of the child Statistics do not show so favorably as to the lives of mothers only a few more children are born of whom a large [illegible] centage die later The game is not worth the candle Statistics come largely from the hospitals Another argument against this is, if we establish this rule the mortality will be very high, because most patients cannot be taken to hospitals

Dr Stephen Harnsberger, Catlett I have had three craniotomy and three placenta praevia cases, the mothers all lived and the children all died In all six cases cesarean section should have been done It is a justifiable and proper operation

Dr. A B Hooe, Washington, D C Dr Harnsberger did not make it so emphatic as he should, the operation should be resorted to if speedy delivery is necessary, in eclampsia and placenta praevia especially When disproportion between the size of the head and the natural passages exists, cesarean section is always resorted to Perhaps epileptics are sometimes caused by the use of high forceps, or by the child remaining in the birth canal too long I condemn high forceps

Dr W E McGuire, Richmond Every case should be treated according to individual indications I have never seen a case in which placenta praevia was an indication for cesarean section Treatment should be given at the time of the first hemorrhage I have never done cesarean section for hemorrhage, but have done it for dystocia and eclampsia

Dr George Tucker Harrison, Charlottesville I use the abdominal way only in central implantation and in contracted pelvis I have tried the old game of morphin and eliminatives, but the sooner you empty the uterus, the sooner you save the mother

Treatment of Fracture of the Femur

Dr. A R Shands, Washington, D C The chief responsibility is to prevent shortening, and muscle spasm the chief factor to overcome, a spastic contraction of the most powerful muscles in the body Overcome the muscle contraction, hold the fragments in place and apply a spica from the nipple to the toes Make a skiagram to see if leg is in proper position If you cannot hold the fragments in apposition by reason of obliquity of the fracture, then operate

DISCUSSION

Dr S S Gale, Roanoke Recently I visited a hospital in Colorado, and there saw three or four cases of fracture of the femur I learned a point worth remembering, the use of a Buck's extension with excessive weight, 30 to 50 pounds, depending on the muscular strength to be overcome I have tried it in one case, in a muscular colored man with fracture near the neck of the femur My assistant put it up first, with 15 or 20 pounds Pain persisted I put on 50 pounds, the limb came down the muscle was paralyzed, and the man obtained immediate relief from pain I kept it on two weeks or more, when the muscle was thoroughly paralyzed, then I used a plaster cast I prefer to plate or wire by the open method Interposition of muscle tissue aften prevents union

Dr George Tully Vaughan, Washington, D C It is much easier to use this in children than in adults I have used Lane plates almost constantly in place of wire, they do not slip as wire does Nevertheless they are necessary evils Do not use them unless necessary

The Work of Health Departments

Dr E C Levy, Richmond The Virginia Public Health Association has the most important function of any body of men in the state Health officers should not only be trained in practical science but should be conversant with the business end as well Training as a physician does not train one as a health officer, but it will be many years before we have other than practicing physicians as health officers in the smaller places If he cannot acquire the information before, he must do it after he is inducted into office

A System of Segregated and Protected Prostitution

Dr P S Schenck, Norfolk The scope depends on the size of the town and the amount of funds The per capita taxation required is greater in small communities than in large, 50 cents per capita in the smaller, and 40 cents in the larger cities per year This expenditure pays large dividends in the way of inducing investments There are only two cities in the United States, so far as I know, in which a systematic inspection of the segregated area is in operation, these are Norfolk and San Francisco We require the landlady to report the arrival or departure of any inmate On complaint of infection we send a police officer and a doctor We have four inspectors There was so much complaint from the U S Navy of men becoming infected at Norfolk that we had to do this We invoked the aid of the police department and made a canvass of every house in the city We inspect and take swabs, if clean we issue cards good for fifteen days Each inmate is reported, and cannot "have company" unless she has her card posted in the room A fine of $50 and costs is imposed for failure to comply with these requirements, repeated frequently if need be If an inmate is found infected, she is put in quarantine and in charge of a physician If she cannot pay she is treated by the city Venereal diseases are not legally reportable here, but often are reported If complaint is made to us of infection, and the man will cooperate, we send a police officer with him He identifies the woman, and she is quarantined and treated Our system has proved eminently satisfactory

Dr E G Williams, Richmond Our work has reduced the number of typhoid cases in the state nearly one half, and the cases of tuberculosis are reduced about 4,000 Curiously diphtheria has apparently increased I think this is due to giving immunizing doses, which do not prevent the recipients from becoming carriers The number of cases has increased, but the death rate has decreased from 7 to 3.5 per cent

The Cause of Death in Intestinal Obstruction

Dr. Harvey B Stone, Baltimore Three classical ideas are maintained (1) general infection, (2) overwhelming nervous centers, (3) toxic absorption As to the third, ideas have been vague, and our experiments on dogs bear on this particular idea We were forced to the conclusion that the toxic material was the secretion from the mucous membrane, the obstruction leading to a perversion of its physiology, somewhat analogous to exophthalmic goiter These observations confirm clinical experience as to drainage We found that the toxin is much richer in the cases of high obstruction than in low To correlate our experiments, we were fortunate enough to obtain similar material from two cases in man This was as toxic as that from the dogs

Dr J S Horsley, Richmond I have always had a suspicion that this material was in the mucous membrane, but why does it act this way? Is it caused by the interference with the lumen or with the circulation? I think it must be with the circulation It has a practical bearing on, say, intussusception In two cases of this I resected, and the patients recovered, while in a reduction in two cases, one patient died with high temperature and cerebral symptoms

Blood Pressure

Dr. J W Preston, Roanoke I addressed a series of questions to five authors of leading text books 1 "Do your observations lead you to believe the normal blood pressure during pregnancy, preceding the onset of labor, to be higher than in the non pregnant?" B C Hirst and J C Edgar hold that there should be no rise, J C Webster states that there is usually a slight rise, E C Davis says that there is a uniform rise of from 10 to 30 mm 2 "Do you find toxemias leading to eclampsia, either in the presence or absence of albuminuria, uniformly accompanied by an abnormal rise of blood pressure?" All replied in the affirmative, including J W Williams, though Davis notes in certain desperate cases that it may be abnormally low 3 "Do you consider blood pressure estimation of material aid in the prognosis and treatment of such cases?" All replied in the affirmative, and Williams adds, "The higher the blood pressure in the preeclamptic state, the less amenable I consider the patient to prophylactic treatment."

KENTUCKY STATE MEDICAL ASSOCIATION

Fifty Seventh Annual Meeting, held at Louisville
Oct 28 31 1912

The President, Dr D O Hancock, Henderson, in the Chair

The officers elected were named, November 9, page 1726

Serum Treatment of Cerebrospinal Meningitis

Dr. Donald K. Clark, Louisville The curative effects of the serum depend on its early use This, in turn, depends on the early diagnosis All suspicious cases should be subjected to lumbar puncture, and the spinal fluid examined for the meningococcus By the early use of the serum the mortality may be reduced 15 or 16 per cent The introduction of fluids into the spinal canal is never devoid of danger No hesitancy should be felt about giving repeated doses of the serum A case that does not respond to four doses may respond to eight or more

Typhoid Carriers

Dr A. Dixon, Henderson All carriers should have individual articles which they use in every day life, such as dishes, basins, towels, etc Water closets used by carriers should receive regular and systematic disinfection, and carriers should be required to disinfect their hands after each visit to the water closet Thoroughly washing with soap and water suffices in carriers of some occupations, but if there is a possibility of the carrier handling foodstuffs, an antiseptic solution should be used in addition The administration of typhoid vaccine as a cure for carriers seems to give better promise than any other procedure

Blood Pictures in Tuberculosis

Dr. Everett Morris, Sulphur Blood pictures in pulmonary tuberculosis show, as a rule, a low percentage of hemoglobin, a normal or increased number of erythrocytes, a subnormal color index, an increased number of leukocytes, an increase in polymorphonuclears and a decrease in mononuclears, small lymphocytes and eosinophils as the disease progresses The transitional cells appear to remain constant without regard to stage, extent or activity of the infection. Leukocytic pictures in pulmonary tuberculosis portray more accurately the patient's resistive force than does the extent of the lesion Arneth's differential neutrophilic count is practical and no examination is complete in tuberculosis without the blood pictures

Infant Mortality, Its Causes and Prevention

Dr Henry Enos Tuley, Louisville As far back as 1893 it was shown by Eross, who studied the statistics of 1,430,056 children in sixteen large European cities, that 10 per cent of the children born alive die within the first four weeks of life This mortality was greatest on the first day and diminished each day as the child grew older Further, congenital debility is given as a cause of death in 54 per cent of infants which died within four weeks after birth Prof Irving Fisher states that in a series of 100 cases of premature births, 40 were preventable, of 100 children dying of congenital debility 40 might have been saved and of 100 children dying of venereal diseases 70 might have been saved

The question of feeding the new born infant is paramount in a discussion of this subject More cases of athrepsia, malnutrition and acute gastro intestinal disturbances with a fatal ending have their origin in an improper diet during the first few weeks of life, than from any other cause The community plan of caring for infant welfare is productive of the greatest good in the reduction of infant mortality Wilbur Phillips has estimated that the average cost of caring by preventive methods for the health of one baby for one year is $6 and the average cost to parents in Milwaukee to rear babies to the average age to which they die (about four months) of paying for confinement for baby carriages doctor's bills etc is $120 He estimated then that saving the death of one baby would pay the community for providing medical and nursing supervision for twenty babies for an entire year By establishing stations in the localities where statistics show the greatest morbidity and mortality to be which would be a center for dispensing clean, cold milk for caring for the mothers of all babies in the district, and for providing medical and nursing service, to be paid for by the city, many babies will be saved to society and a great financial saving brought about to the community

Self-Medication

Dr. J H Hohnstedt, Fort Thomas When the laity awakens to a realization of the harmful effects in the indiscriminate use of self prescribed remedies, and gives them up for those scientifically indicated after an intelligent diagnosis has been made, we may look forward to a better race in which all preventable diseases will gradually be eliminated The laity will learn that hygienic conditions and a properly prescribed remedy are essential to the preservation of health and the cure of diseases The admissions to our insane and blind asylums will gradually decrease in number and our criminally defective will become fewer, thus permitting our asylums to become hospitals and homes for the sick and aged

The Passing of Destructive Operations in Obstetrics

Dr Edward Speidel, Louisville Craniotomy is justifiable on the living child in undoubted cases of hydrocephalus Under all other circumstances delivery should be effected by abdominal cesarean section, if not possible by the vaginal route A destructive operation is necessary on the dead child in impacted shoulder presentations In all other cases, delivery should be attempted by version and in extreme cases of pelvic contraction even the dead child should be delivered by cesarean section, as the safest and most conservative method for the mother

Endometritis

Dr William L Mosby, Bardwell Curettage of the uterus should be done in the infectious and chronic forms of endometritis that have proved rebellious to local and constitutional methods of treatment When inflammation exists in the adnexa with immovable uterus, sensitive to the touch there is increased danger of lymphangitis or peritonitis The dull curet, like the uterine sound in these cases, is equally to be condemned as it opens up new avenues, supplies fresh material for infection and is powerless for good This important gynecologic operation should be done only under proper surgical environment and with sufficient surgical skill to promise the patient all that modern gynecology offers

Pellagra as a Public Health Problem

Dr O P Nuckols Pineville A commission should have power to prosecute all measures of protection of the public, by having the power to isolate and remove to the hospital all patients with pellagra, within the hospital district, in whom a positive diagnosis can be made All data connected with every case should be collected carefully and preserved, and each case made a special study The commission should act in conjunction with the state board of health and the county boards of health in carrying out all measures of general sanitation in the pellagra district The treatment carried out at the pellagra hospital should be of the most approved methods, including hydrotherapy and all other adjuncts that will be of advantage in arresting the disease Until pellagra patients are segregated and cease to be a source of further spread pellagra will grow and flourish but if it is dealt with promptly scientifically and humanely, it will soon be a relic of history

Pellagra in Eastern Kentucky

Dr. J H Hendren, Cary The use of Indian corn and its products as a food has nothing to do with the cause of pellagra or with the continuation of its symptoms even after it has been caused by some other agency There is probably an intermediate host but the evidence at the present time is not sufficient to incriminate the *Simulidae* of Sambon No physician is justified in diagnosing a case as pellagra until the eruptive stage has appeared Pellagra is not contagious in *utero* nor can it be transmitted from mother to child through the medium of mother's milk A large percentage of the cases appear to be associated with or are in the wake of some other disease as measles [illegible] The disease is caused by a microor [illegible] germs of the disease are located principally in the brain and spinal cord, and ordinarily do not circulate in the blood stream The cure for pellagra will be found in the use of arsenical compounds, possibly one not yet brought out, and most probably one used intravenously Until we know more of the cause of pellagra, segregation and prophylactic measures are useless The eruption of pellagra is not due to the germs of the disease *per se*, but to the toxins generated by them A large number of patients seem to develop an immunity to the disease, each attack growing less and less severe until the disease disappears All proof of its transmissibility from person to person seems negative, although there is strong evidence that it is a house infection

Acute Suppurative Otitis Media, Its Recognition and Treatment by the General Practitioner

Dr C T Wolfe, Louisville An important requisite to an early diagnosis is the ability to recognize a normal drum membrane An early otoscopic examination will show a red and thickened drum membrane which, as the suppurative process advances, bulges into the external auditory canal, depending on the amount of secretion within the tympanic cavity Soon the bulging seems to become particularly distinct in one or more segments, more especially in the posterior superior quadrant, in the more severe types large blebs may be present in the layers of the tympanic membrane An incision should be made at this time, extending from Schrapnel's membrane to the floor, through the bulging part This is imperative from the fact that should spontaneous rupture be permitted to occur, irreparable damage may be done to the drum membrane and other intratympanic parts from the pressure of the secretions This operation is not difficult and the details are readily learned We may look on the prognosis from a favorable point of view, provided that the case has been properly managed and has received modern treatment The treatment resolves itself into two parts The first consists in the alleviation of pain, evacuation of the pus from the middle ear, the maintenance of proper drainage and, if possible, the prevention of complications The second consists in the removal of such factors as are conducive to a recurrence of the disease

Diagnostic Errors in Diseases of Children

Dr Robert H. Moss, Henderson Every pediatrician of large experience knows that the pain of pleurisy and pneumonia in children is referred to the abdomen as frequently as to the chest. There are three things that a physician should always think of in the case of a child with an acute abdominal pain—pneumonia, appendicitis and intussusception—and I would emphasize most strongly the importance of careful and repeated examination of the lungs in all acute abdominal affections in early life The inhalation of foreign bodies often gives rise to puzzling clinical pictures The infant may have a suffocative attack, or paroxysm of coughing from which he quickly recovers, later on the symptoms of an acute bronchitis or pneumonia become manifest, and all too often the causative relation of the foreign body is unsuspected I treated an infant for a bronchopneumonia for about two weeks when one day during a severe paroxysm of cough, a wheat grain was expelled, after which recovery rapidly supervened

Rachitis is considered by some authorities to be more frequently overlooked than any other disease Doubtless one reason for the widespread failure to recognize this condition is that our attention has been generally centered on the changes, in other words, one of the terminal events It is practically agreed by all pediatricians that underlying the syndrome there is a dietetic error, with a superadded digestive disturbance Some authors contend that the accompanying indigestion is always present and is the chief contributory factor

Management of Puerperal Eclampsia

Dr W B Moore, Cynthiana Many of the measures advocated from time to time in the management of eclampsia are worse than useless Pilocarpin, at one time held in high esteem, is a dangerous drug in this condition It strongly predisposes to pulmonary edema The consensus of opinion to day favors rapid delivery The point in dispute is the method of emptying the uterus This must depend on the condition of the cervix, the time of pregnancy, the surroundings of the patient and the skill of the attending physician We believe that the greatest good to the greatest number will result from a campaign of education Instruct the women of this country that any variation from normal health during the period of gestation may be the beginning of a serious condition, and that the safety of each lies in following the instructions of an intelligent physician If this procedure is faithfully carried out, the management of eclampsia will be solved without the dangers of chloroform narcosis and surgical operations, in the desperate attempt to save these patients from an untimely grave

Management of Placenta Praevia

Dr Walker B Gossett, Louisville The first danger in placenta praevia is that of hemorrhage which may occur without any warning, the patient being at rest, or following coughing, sneezing, straining at stool or lifting The degree of collapse will generally depend on the extent of the bleeding The second danger is that of sepsis following the delivery, and these cases are more prone to puerperal sepsis, therefore absolute surgical obstetric asepsis must be observed, no objection can be made to the use of rubber gloves in these cases, as they have gone beyond physiologic labor and are in a pathologic condition The first treatment for ordinary domestic practice, when the bleeding has to be arrested before labor has begun and when the cervix is not dilated, is the tampon, plug both cervix and vagina When the cervix is dilated or dilatable to the extent of permitting two fingers being passed through it, I perform podalic version and deliver As to rupturing the membranes, this should be done to the side if possible, if not, go through the placenta Do not be hurried in the extraction of the child The child's thigh and breech should be pushed through the cervix by the uterine contractors, not dragged through, unless there is some reason for making a quick delivery I always depend on gauze plugging and my hand in these cases

Perinephritis

Dr. W L Cash, Princeton In the treatment of perinephritis, the patient should be put to bed and kept as quiet as possible throughout the attack Hot fomentations or an ice bag should be applied over the affected side, purgation should be by means of calomel, and urinary antiseptics should be given If these measures fail to bring about resolution, and suppuration becomes inevitable, a poultice may be used to hasten the formation of the pus When the abscess forms, the treatment is distinctly surgical There should be free incision, thorough exploration and adequate drainage The toxemia should be combated by generous diet, stimulants and tonics.

(To be continued)

COLLEGE OF PHYSICIANS OF PHILADELPHIA

Meeting held Oct 2 1912

The President, Dr. George E. deSchweinitz, in the Chair

The Spinal Cord in Pernicious Anemia

Dr. Robert N Willson, Jr It is well to remember that there exist spinal cord and perhaps brain changes in every case of true pernicious anemia, and that many cases that fail of prompt recognition, owing to nervous symptoms, would at once become clear if this fact were kept in mind. The likelihood that both the clinical picture and the cord degeneration are secondary to and the direct result of a definite toxemia has been hinted at, but the nature and source of this toxin and its method of action are still matters of speculation In my case there is a marked clinical indication of a pathologic intestinal process dating back to childhood and terminating only in the gastric crises which indicated, perhaps, the final influence of the auto intoxication on the spinal cord. It seems evident that the toxemia led to the pernicious anemia, the spinal cord degeneration and sclerosis, and the fatal termination of the case

Of no slight interest is the series of instances in the patient's near and immediate family connection of pathologic clinical pictures which suggested a definite relation between the pernicious anemia and combined sclerosis in my patient, the father's arteriosclerosis and uremic "stroke," the mother's aortic insufficiency and hepatic cirrhosis, with the renal sclerosis and angina pectoris of one aunt, and the pernicious anemia of another, to say nothing of the death of a third aunt (all three sisters of the mother) in an advanced stage of locomotor ataxia The working of syphilis through the gastro intestinal tract and its influence on the blood and on the spinal cord through a gastro intestinal autotoxemia have not been so thoroughly considered, and this theory is offered not without a certain measure of plausibility in the case under study

The Topography of the Valves of the Heart as Shown by the Roentgen Ray

DR. GEORGE FETTEROLF and DR GEORGE W NORRIS In the method adopted frozen sections of the thorax of formaldehyd hardened cadavers were cut into horizontal sections an inch in thickness Both sides of the valve leaflets of the exposed sections were painted with thick lead paint and photographed with the Roentgen ray Fifteen bodies were thus studied with a view to determining the normal relationship of the cardiac valves to the anterior thoracic wall Inasmuch as many of the bodies studied revealed pathologic topographic relations of the thoracic viscera, no normal standard could be established The communication is therefore made in the nature of a preliminary report with a view to describing a hitherto unemployed and entirely feasible method of studying the position of the valves of the heart in health and disease

Physical Examination of the Liver

DR JOSEPH SAILER Examination of the liver involves (1) The position of the upper border of liver dulness, (2) its contour, (3) the position of the lower border of liver dulness, (4) the position of the left border, (5) the character of the edge, (6) the character of the surface, (7) the palpability of the liver posteriorly which involves bimanual palpation, (8) the motility of the liver, and (9) the existence of pulsation

DISCUSSION

DR. HERMAN B ALLYN In one of two cases seen last winter the patient was a boy who had a large liver as the result of cardiac disease The boy developed late in the disease a fluctuating tumor on the surface of the liver at the usual site of the gall bladder This was supposed to be an enlarged gall bladder, but later there appeared also other nodules about the size of marbles The mass was distinctly fluctuating and, inasmuch as the blood gave a positive Wassermann, we looked on it as possible softened gummata But at autopsy we found cysts beneath the serous coat of the liver I never before saw nodules of this size and due to this cause The other case was that of a woman with secondary sarcomatous mass developing beneath the left border of the liver which moved freely with respiration It was found to be a mass connected with the omentum and not attached to the liver

11 Metastasis of Hypernephroma in Nervous System Jacksonian Epilepsy Caused by Such Lesion J Collins and R G Armour New York
12 Metabolic Observations on Amyotonia Congenita J C. Gittings and R. Pemberton Philadelphia

1 **Tertiary Syphilis of Liver** —Syphilis of the liver, McCrae says, presents a very varied clinical picture with prominent general symptoms in many cases, of which loss in weight is marked. The duration of the symptoms may be prolonged and there may be periods of improvement. Fever is a common occurrence There are features suggestive of hepatic disease in the majority of the cases Enlargement or tumor is the most common This may suggest other conditions, especially malignant disease General enlargement and the occurrence of nodules or large rounded masses are the most common A striking feature is the relatively marked enlargement of the left lobe as compared with the right The diagnosis may be obscured by other diseased conditions or the liver condition may be interpreted wrongly Ascites is sometimes a difficulty Knowledge of the features of hepatic syphilis and the therapeutic test are important aids Treatment can influence the syphilitic process, but not its results (cirrhosis amyloid)

2 Abstracted in THE JOURNAL, July 13, p 139

4 **Weight Curves in Typhoid** —The results of Coleman's observation are summarized in one sentence It is possible to maintain patients suffering from typhoid in weight equilibrium throughout the entire course of the disease by giving them sufficient food

5 **Scarlet Fever, Diphtheria and Measles** —During the last year observations were made by Bell on over 300 cases of scarlet fever The following summary indicates the findings in the so called classical symptoms and diagnostic signs Scarlet fever 315 cases Onset with vomiting 50 per cent , onset with headache, 4 per cent onset with sore throat 65 per cent , eruption, whole body, 46 per cent , eruption, partial 35 per cent , mouth pallor, 57 per cent rash on soft palate, 38 6 per cent , membrane on tonsils, 29 per cent , papillae enlarged 56 per cent , glazed tongue, 17 7 per cent anterior cervical glands enlarged 95 per cent , submaxillary glands enlarged 72 per cent , eruption gone from body, five and one half days, desquamation began in six and three quarter days, blood count, leukocytes average, 17,000, polymorphonuclears, average, 78 per cent., large lymphocytes average, 6.3 per cent , small lymphocytes, average, 10 1 per cent , eosinophils average, 2 per cent , albumin, 11 per cent , granular casts 4 per cent , hyalin casts, 2.5 per cent , blood cells, 4 per cent myocarditis, 6 per cent irregular heart, 3 per cent , murmurs 8 per cent , mastoiditis (no facial palsy in this series), 1 per cent , *arthralgia (all cases had an immunizing dose of diphtheria antitoxin)* 6 per cent acetone 49 5 per cent diacetic acid, 22 6 per cent , indican, 73 per cent temperature gone in five and two third days, nephritis, 2 per cent The average white count of patients who died was 17 262 Preponderance of the staphylococcus may have influenced all leukocyte counts

The so called Pastia's sign in this disease namely, the accentuation of the rash in the normal folds especially on the anterior surface of the elbow was not noticed except in a few instances, so that no significance has been attached to it Of like importance is the Rumpel Leeds phenomenon or the hemorrhages at the elbow from compression of the upper arm by means of a bandage

With the use of the ordinary antistreptococcic serum made up of streptococci not from scarlet fever patients Bell has noticed little benefit even in doses of 80 or 90 c c in twenty four or thirty six hours If he says it is used at all it should be made from the streptococci from blood throat or glands of scarlet fever cases The results with these stock vaccines were not brilliant Patients using vaccines had no local treatment Irrigations were employed for the others Except in one or two instances he could not see that the discharge from ears was modified by the vaccine, and on the whole those having local treatments ran a shorter course The dosage in each case was started with about 200,000 and each succeeding dose was doubled at intervals of from two to ten days according to indications This was carried up to 128,000,000 in some cases

True relapses or reinfections were not observed, but delayed rashes occurred in one or two instances Eighteen blood cultures were made during the year from scarlet fever patients Of these nine were negative In the other nine cases the *Staphylococcus pyogenes aureus* was recovered seven times and the *S pyogenes albus* twice The throat and nose cultures almost uniformly showed the presence of staphylococci, occasionally mixed with a few streptococci Twelve cervical glands of scarlet fever patients were aspirated with aseptic precautions in an effort to corroborate the claims of Vipond made in the spring of 1911, that he had found the specific organism of scarlet fever in the glands of patients suffering from this disease The cultures were sterile in nine cases, the *Staphylococcus pyogenes aureus* was isolated twice and the *B pyocyaneus* once

The following summary shows observations made on 76 cases of diphtheria Onset with sore throat, 84 per cent , onset with vomiting, 33 per cent , membrane on tonsils, 85 per cent , membrane on soft palate, 36 per cent , inflammatory swelling, 30 per cent , membrane gone on the average in two and seven elevenths days, temperature normal on the average in three and three quarter days, erythema (not from serum), 5 per cent , urticaria (not from serum), 14 per cent , otitis, 5 per cent , albumin, 12 per cent , adenitis, 47 per cent , paralysis, soft palate, 5 per cent , paralysis of other muscles, 4 per cent , myocarditis, 16 per cent , endocarditis, 28 per cent , slow pulse, 4 per cent , arthralgia, 2 6 per cent , acetone, 28 5 per cent , diacetic acid, 14 per cent , indican, 32 per cent , serum rashes, 16 per cent , antitoxin, average dose, 40,000 units, highest dose, 355,000 units, blood count leukocytes, average, 13,033 The mortality for diphtheria as reported up to Jan 1, 1912, was 3⅓ per cent , while for scarlet fever it was 0 5 per cent

8 **Granulomatosis of Stomach**—The authors conclude that linitis plastica is not a new kind of morbid process, but is the effect of some chronic infective agent whose nature has not yet been determined The process at work is often akin to the granulomatous process which occurs in mediastinal tissues and elsewhere, it is akin to the changes which occur in the course of some forms of tuberculosis and of diffuse sclerotic types of tertiary syphilis, and it is occasionally followed by the development of an epithelial growth, just as is sometimes noticed as a sequel to tuberculosis and syphilitic lesions The disease known as linitis plastica, or cirrhosis of the stomach, only demands a separate name because it is clinically a simulator of true carcinoma Its prognosis should be more favorable and its treatment by the surgeon more effective The small degree of epithelial overgrowth which may be regarded by some observers as carcinomatous, is not really any greater in extent than are the atypical proliferations of epithelium which are known to result from the subcutaneous introduction of certain irritant lipoid soluble bodies The suggestion is that the abnormal cells in this granulomatous tissue are pouring out substances which may excite the overgrowth of the glandular epithelial cells in the same way that many bodies (dimethylamidoazobenzol, amidoazotoluol, a naphthylamine, methylimidazol, indol and skatol, etc.) were found to excite epithelial overgrowth by Wacker and Schmincke in 1911 This renders the development of carcinoma as a secondary process on a preexisting (often long persistent) submucosal disease quite intelligible, and emphasizes the view which the authors would point out that the malignant change in this, as in "Hodgkin's disease," and in many lymphosarcomas (also in Paget's disease of bones), is not an inevitable sequence, but is superimposed by the succumbing of certain other tissues to the continued noxious action of abnormal cell products

14 *Pyelonephritis of Pregnancy and Puerperium J W O Connor Worcester Mass.
15 Adjustable Knee Support H W Marshall Boston.

14 **Pyelonephritis of Pregnancy and Puerperium.**—From the study of twenty nine cases and a review of the literature, O'Connor concludes that infection of the pelvis of the kidney invariably *involves the parenchyma Owing* to its anatomic relations the right kidney is the more vulnerable The disease is much more frequent than supposed, O'Connor estimates that it occurs once in every 3,000 cases Malnutrition, constipation and tonicity of the abdominal muscles are *predisposing factors*, tendency to renal abnormalities on the right, dextro torsion of the uterus and predominance of positions in the right oblique diameter favor the infection of the right kidney Infection by the colon bacillus is the most common type, direct transmission through the intestinal walls being the probable mode of entrance The pathologic picture shows the pelvis and ureter dilated with pus and miliary abscesses in and beneath the cortex The cardinal symptoms are smarting micturition, chills, fever, nausea and vomiting, pain in the loin *and elevation of pulse The urine is turbid*, purulent and albuminous Tenderness in the region of the kidney is always present Enlargement of the organ can be demonstrated in about one fifth of the cases Abortion and surgical kidney are the most common complications The diagnosis can generally be made on physical signs and urine analysis, the differentiation from appendicitis presenting the greatest difficulty Prognosis is usually good for the mother and less favorable for the child Treatment by rest, sedation, catharsis and urinary antisepsis has met with success The use of vaccines and pelvic lavage, if of any real value at all, entails dangerous delays and, being extremely technical, is beyond the scope of the rank and file of the profession Early operation in cases that assume a surgical aspect is to be strongly recommended

19 **Operative and Postoperative Tonsillar Hemorrhage**—Franklin says that no patient should be permitted to leave the operating table until both cavities are dry Every case of delayed primary or secondary hemorrhage he has encountered has given evidence, while on the operating table, of a tendency to bleed At present he sutures every case in which, after ten minutes from the enucleation, the bleeding has not been stopped He sees no possible objection to this procedure The deformity is no greater following sewing than due to the cicatricial contraction of the average healed case Following hemorrhage it is well to put the patient on a saline injection given by the Murphy drop method, and if the loss has been considerable the foot of the bed should be elevated, and morphin given subcutaneously He emphasizes the importance of treating tonsillar hemorrhage surgically, i e , by mechanically compressing the bleeding vessels The Mikulicz tonsil hemostat *is an old fashioned, barbarous instrument When applied it is*

extremely uncomfortable to the patient and has a constant tendency to become dislodged If held sufficiently tight to retain its position, it keeps the patient awake with saliva flowing from his mouth, pain over the wound and angle of the jaw and causes the sponge to adhere firmly to the cicatrizing surface Franklin does not consider it safe or good practice to rely on chemical means for control of bleeding It must be remembered that vaso constrictors cause a secondary dilatation of the blood vessels

21 **Tonsil Surgery**—Stephenson believes that a tonsillectomy is as severe, and should be classed, in point of gravity, the same as an appendectomy He holds that all hypertrophied tonsils without lesion or grave complications should be removed All tuberculous tonsils with lesions should be treated medically and never surgically All tonsillectomies should be performed under general anesthesia, unless the condition of the patient is such that a general anesthetic would be dangerous All tonsillectomies should be hospital cases, i e, the operation should be performed in a hospital All tonsillectomies should be followed by the passage of an adenoid curet All curettages following a tonsillectomy should be followed by the passage of the finger The hot wire ecraseur should never be used

26 **Pellagra in California**—The most important conclusion reached by the authors is that pellagra has been found to exist in three cases out of 180 consecutive cases admitted to a private sanatorium None of the three cases was imported to the western coast, but evidently originated there None of the patients belonged to the poverty stricken class of people In all cases, however, nutritional disturbances preceded a long time the development of definite evidences of pellagra In one case there is a definite history of long use of vegetable oils and this case happened to be the most acute, affecting the nervous system to the greatest extent and terminating fatally in the shortest time All three cases evidently originated without any infection from similar cases and there is no evidence that any one was so afflicted as a result of contact with them While it is not claimed that pellagra had been a causative factor in the mental or nervous breakdown of any of the three cases, it is evident that in every case it has greatly and in a detrimental way influenced the mental and nervous condition Cacodylate of sodium, tried in two of the three cases has not had any lasting beneficial effect on the disease The same is true of all other treatment attempted

64 **Chronic Lymphatic Leukemia**—The urine in the case studied by Wesson has been reduced in quantity, dark yellow to orange in color, turbid, specific gravity 1 025 acid reaction no albumin or sugar There is generally, in a twenty four hour specimen a heavy, voluminous, brick red sediment of amorphous urates Not infrequently uric acid crystals are present A search for ferments in the urine disclosed the fact that there must have been some enzyme present (maltase) which had broken down the maltose molecule and that a proteolytic ferment was also present There was no amylolytic ferment present The presence of a fat splitting enzyme was suggested but was not very positive at first then it was quite evident that a lipase was present

65 **Hemoptysis in Tuberculosis**—Although there exists considerable difference of opinion as to the causes of hemoptysis Frazer says there is practical uniformity in the method employed in the treatment of this condition despite the use of drugs apparently antagonistic in their action and other minor details The first indication is to reduce blood pressure As hemoptyses are sometimes preceded by a sense of tightness in the chest or by the presence of blood streaked sputum it may be possible to prevent their occurrence by instituting [illegible] rest and by the administration of a drug such as the nitrites

—with the view of decreasing vascular pressure Either of the following may be used

℞	Gm or c c		
Sp nitroglycerin	1		♏ xv
Aquæ	60	or	℥ ij
M. S Dose ʒ j			

℞	Gm or c c		
Sodii nitritis	1		gr xv
Aquæ	60	or	℥ ij
M S Dose ʒ j			

A teaspoonful of either of the above may be given every four hours for two or three days

More commonly, perhaps, the patient receives no warning and the physician is summoned to treat an active hemorrhage In the presence of this condition the indications are three in number to secure absolute physical rest, to quiet the fears of the patient, and to lower the blood pressure, attempting in this manner to favor the formation of a clot, which is nature's method of checking hemorrhage This means that the patient must be put to bed and all unnecessary movements on his part must be avoided, he is not allowed to get up to attend to the demands of nature, nor is he allowed to talk A comfortable position should be assumed usually the semi recumbent posture (with one or two pillows under the head) is best, and the patient should be assured in a few words that there is little cause for apprehension Frazer's practice is to break one of the little "packages" of amyl nitrite, holding it for several minutes under the patient's nostrils The patient should also receive atropin gr 1/50 hypodermically, and this dose may be repeated two or three times within the next twenty four hours In place of atropin, nitroglycerin may be administered hypodermically in doses of gr 1/100, repeated at short intervals, at first every half hour or hour, for three or four doses, later less frequently After vasodilation has been obtained, more permanent effects may be secured by the use of sodium nitrite, gr j, every three or four hours Morphin, although used considerably in hemoptysis, should not be resorted to as a routine measure It is indicated if the cough be troublesome, but its field of greatest usefulness is in those cases in which excessive nervous irritability exists It is customary, at the onset of a hemorrhage, to place a light ice bag over the precordium, with a view to quieting the heart's action

There is no specific diet for patients with hemoptysis, but the amount given should be small and fluid in character (milk in small quantities and egg albumen are suitable), especially is it necessary to restrict the diet during the first twenty four hours While depletion through the intestines by means of catharsis has been advised and is theoretically indicated, it is better to wait twenty four hours before attempting to move the bowels on account of the exertion which this action imposes on the patient Also examination of the chest should not be undertaken, or should be restricted to auscultation, under no circumstances should percussion be practiced. As to the length of time that a patient who has had an hemoptysis should stay in bed, there exists considerable difference of opinion it is safer to insist on rest in bed for twenty four to forty eight hours after the expectoration of post hemorrhagic clots has ceased.

72 **Direct Transfusion**—Soresi insists that transfusion should not be resorted to only when the patient is in extremis, surgeons should train themselves on animals in conservative surgery of the blood vessels before attempting transfusion in human beings, vein to vein method is to be preferred, and the use of a vein of the neck of the recipient is the only physiologically correct method to be adopted, except when not suitable during surgical operations In hemorrhages there must be a distinction between hemorrhages which can be completely checked and hemorrhagic diseases, in the former saline solution should be administered immediately as first resort and during or before transfusion, in the latter, transfusion should be resorted to before other liquids are introduced into the system, because the blood is used as a hemostatic and should not be diluted, in the greatest number of hemorrhages saline solution is sufficient to save the patient and transfusion should be resorted to only when the surgeon thinks that the hemopoietic organs of the patient would be unable to supply, in a reasonable time, the morphologic elements indispensable to life In diseases in which the blood is loaded with poisonous products, transfusion is very useful, provided that the central nervous system is not too seriously injured and blood is let out during or before transfusion is resorted to Transfusion is a great help to patients who are considered bad surgical risks, and it must be performed during the operation A vein for both donor and recipient should be used, anastomosing the distal part of the donor's vein with the proximal part of the external jugular of the recipient In this way the radial artery is saved and it is easier to find a donor Obviously there may be cases in which it is advisable to use the radial artery of the donor, and transfusion will be very satisfactory, but, when possible, vein to vein should be used, always preferring the external jugular for the recipient

79 **Correction of Nasal Deformity**—The septum in Glogau's case was prepared as for submucous resection by applying a 20 per cent cocain solution and a 1 to 5,000 epinephrin solution, with cotton pledgets to the Schneiderian membrane The usual incision was then made on the right side, but the knife was carried right through the cartilage toward the mucous lining of the left side without, however, injuring the latter The cartilage was then elevated from the mucous lining on the left side, and by means of a strong pair of scissors an incision was made at its upper and lower margins The cartilage flap, covered by the mucous lining of the right side, was thus attached at its posterior part only The nostrils were now plugged with a piece of cotton, and the back of the nose cleaned aseptically A 0 5 per cent cocain solution, containing a few drops of epinephrin, was then injected hypodermically at the middle of the nose toward the tip A transverse incision of about 15 mm was then made at the lower end of the nasal bones Through this incision, by means of a knife, the subcutaneous tissue was separated along the back of the nose down to the tip A sharp spoon was then introduced into this pocket and the cartilage at the tip of the nose curetted. The external wound was then covered by a piece of gauze The cartilaginous flap was now severed from its posterior attachment and put into a physiologic salt solution By means of a Bier's skin grafting knife, the superficial epithelial layers of the mucosa were then removed, and the cartilage, covered by its perichondrium, shaped by means of a pair of scissors to fit into the deformity The cartilage was then inserted into the deformity, and the transverse incision closed The wound was covered by a small piece of iodoform gauze and adhesive plaster The mucous lining over the bony part of the deviated septum was then elevated on both sides, and the bony deviation removed by submucous saws The septal mucous lining of the left side remained intact, while on the right side there was a loss of substance corresponding to the piece of cartilage removed with its right sided mucoperichondrium The nasal cavities were then painted with a 10 per cent. oily solution of iodin and packed in the usual way The intranasal packing was removed after forty eight hours, and the dressing of the external wound was changed every day After the fourth day

the ligature began to suppurate and the wound opened again. Healing by granulation took place. The inserted cartilage became permanently attached and the deformity is now considered to be corrected.

83. **Conservative Surgery.**—Schwyzer emphasizes the fact that the kidney parenchyma is not to be considered as free from bacteria even under normal conditions, and second that the kidney substance has a good resistance against bacterial invasion. In operating on the kidney, in draining and otherwise handling it at and after operation, it is well to have these facts in mind.

86. **Nephrectomy Without Drainage for Tuberculous Kidney.**—Mayo emphasizes that every effort should be made to remove the tuberculous kidney without the escape of its contents, and to secure this result an adequate incision is essential. The patient is placed on the sound side with a considerable degree of elevation of the loin. A vertical cut frees the twelfth rib from its posterior attachments and a long transverse incision mobilizes the lower wall of the thorax. In this manner a large kidney can be removed with ease. In some instances tuberculous material will have escaped spontaneously into the perirenal tissues before operation and in such cases it will not be possible to remove the organ without distributing more or less of the tuberculous infection throughout the cavity of the wound. It is in these cases particularly that drainage has resulted so unfortunately and Mayo believes has been an unnecessary procedure. The stump of the ureter is a source of possible infection in the wound, and many surgeons either remove the kidney and ureter completely at the primary operation or they suture the stump of the ureter to the skin for the protection of the wound. For a number of years it has been Mayo's practice to inject 10 to 20 minims of phenol (liquid 95 per cent.) into the ureter. This is distributed down through the lumen and a ureter thus treated will rarely give trouble later. He is convinced that in draining these cases they made a mixed infection possible which was responsible for many of the postoperative conditions. Experience has taught that drainage following operations for tuberculous lesions within the abdomen is unnecessary and usually followed by sinus and fistula; also that draining the cavity from which a tuberculous kidney has been removed gives rise to complications which delay or prevent healing and which may lead to the death of the patient some months later.

87. **Division of Auditory Nerve for Aural Vertigo.**—In this case the incision was made as for a unilateral suboccipital craniectomy. While the operation was followed by only partial relief, Frazier's experience with this operation and with many others in the posterior fossa encourages him to believe that this means of relief should be resorted to more frequently in the persistent and intractable forms of aural tinnitus and vertigo. Before the operation is undertaken, however, one should determine by every means of precision whether the case falls in the category for which this form of treatment is especially applicable.

88. **Arthroplasty.**—Neff reviews the history of arthroplasty, details the embryologic basis on which the operation is performed, the principles involved, the indications and contraindications for its performance, a consideration of the special joints, and then reports three cases, two of ankylosis of the knee and one of the elbow, in which he performed the operation successfully.

89. **Osteo-Arthritis of Spine.**—In diagnosing disease of the abdominal viscera the authors state that no examination is complete without a careful inquiry into the condition of the spinal cord and spinal column, including roentgenography.

90. **Experimental Study of Placenta.**—The evidence obtained by Frank in his investigation favors the view that the placenta is a passive organ for exchange, rather than an active organ of metabolism.

91. **Unsuccessful Surgery of Gall Ducts.**—Gerster opens and drains every dilated common duct. He says that palpation should follow, not precede, incision of common duct. An inflamed, thickened, adherent or shrunken gall bladder should be removed. All cicatricial deposits in gall bladder or in cystic duct justify removal of gall bladder. The presence of many small stones, even though the cystic duct is patulous, indicates that the gall bladder should be removed. The presence of a damaged gall bladder is not an aid but an impediment to exposure of the common duct. Absence of the gall bladder does not constitute an important adverse factor in the subsequent exposure of the common duct.

94. **Function of Corpus Luteum.**—The authors' results support the claim of Fraenkel that the corpus luteum is apparently essential for the development of the fetus during the early part of pregnancy. Attempts to produce an anticorpus luteum serum according to Beebe's method were unsuccessful. Autotransplantation of ovaries yielded success in a rather small percentage of cases. Homotransplantation was considerably less successful. Removal of both ovaries failed to cause either adrenal hypertrophy or microscopic evidence of increased physiologic activity of the adrenals. Attempts to produce experimental rickets by means of transplantation of ovaries were unsuccessful.

4 **Sugar in Cerebrospinal Fluid from Cases of Meningitis**—There is in normal cerebrospinal fluid a chemical substance which reduces Fehling's solution, and this is absent in some cases of meningitis and present in others There appears in the literature of the subject considerable confusion as to the cases in which it is present or absent, and considerable uncertainty as to its value Jacob's experience, based on only a small number of cases, has led him to a definite conclusion on this subject, and he considers such examination to be of definite value The method adopted is to boil together equal portions of cerebrospinal fluid and Fehling's solution in a narrow test tube and allow it to rest in a sloping position In the course of an hour there will be a marked yellow deposit forming a band on the lower side of the tube, and with a little practice one can form a fairly accurate opinion as to whether such band is normal in amount or diminished, where sugar is absent no deposit will occur

Jacob's results are as follows In nine cases of tuberculous meningitis sugar was present in apparently normal amount in one case, was present in diminished amount in seven cases, was present in markedly diminished amount in one case, this was taken only two hours before death In seven cases of pneumococcus meningitis sugar was absent in every case In three cases of streptococcus meningitis sugar was absent in every case In nine cases of cerebrospinal meningitis sugar was absent in two cases and present in diminished amount in seven cases In seven cases of poliomyelitis sugar was normal in amount in one case and slightly diminished in six cases In three cases of mixed septic meningitis, secondary to middle ear disease, sugar was absent in all three cases His conclusions are In pyogenic meningitis, pneumococcus, streptococcus and mixed infection, sugar is invariably absent In cerebrospinal meningitis sugar is absent in the acute stage, but may return in some degree as the infection recedes In tuberculous meningitis sugar is present, except in very rare cases shortly before death, in which stage difficulty of diagnosis rarely exists In poliomyelitis sugar is present

9 **Experimental Purpura.**—As regards the production of experimental purpura Cowell's results have been negative. He believes that the oft quoted positive experiments must, at any rate, not be accepted at present It is doubtful whether benzol has any effect on the blood platelets Although the lytic body at work in purpura is undoubtedly allied to a hemolysin, yet its action seems to be different, since in two fatal cases of purpura neonatorum Cowell has been able to microscope the organs without finding traces of free iron

10 **Operative Treatment of Fractures**—In certain cases, Groves says the method of using an intramedullary peg has great advantages over all others There are two different methods by which the pegs may be introduced into the bone The first kind of peg is comparatively short i e, about 24 cm in length It has a fixed crosspiece, transfixing its center, which keeps the peg from slipping too far into one end or other of the hollow bone One end of the peg is fitted into one fragment of the broken bone Then the other fragment is made to engage the projecting end of the peg, and by bringing the bone fragments into line with one another the muscular tension pulls the ends of the bone together over the enclosed peg, which serves thus to keep the fragments in exact apposition This type of peg can only be used in those cases in which the broken bone fragments are easily separated from one another When it is in position, owing to its shortness, it does not exercise much influence in maintaining the straight axis of the bone

In the class of fractures in which operation is demanded most imperatively, a peg like the one described cannot be employed simply because in these neglected or malunited cases it is impossible to separate the broken ends of the bone sufficiently to insert the peg For these cases Groves has used pegs which are drawn into their place by means of wire traction Each of these pegs is about 4 to 7 cm long, and is perforated in its center by a hole transverse to its long axis Along opposite sides of the peg run grooves in its whole length, and into these grooves the ends of the transverse hole open The size of the hole and groove is one which easily takes a fine flexible steel wire, which, when threaded through the transverse hole, lies snugly in the grooves, so that the whole peg can be slipped into one fragment of the bone, the other fragment brought into apposition, and then, by traction on the wire, the peg is pulled up into position, so that one half lies in one fragment and the other in the other As regards the thickness of these pegs, Groves has a set of thirteen sizes, varying from ⅛ to ½ inch, each size differing from the other by 1/32 inch, and also a set of drills for preparing the bone ends Each drill makes a hole, into which the corresponding peg will slip easily The object of drilling the bone should simply be to clear away any rough, outstanding spicules of bone, and not to actually enlarge the natural marrow cavity It is unnecessary to make the pegs fit very tightly, and the less drilling that is done the better

As regards the method of traction on the wire, in most cases it is quite sufficient to pull on the wire ends, which are rolled round pairs of forceps But if one has to work at the bottom of a deep wound, which makes it difficult to carry this out, the traction may be made by an instrument which winds the wire ends on to two revolving shafts, at considerable mechanical advantage

Groves has used intramedullary pegs made of various materials In comparing the merits of various materials, e g, bone, steel and aluminum, he states that the metal pegs are much the best for animal experiments, because those made of bone or ivory are very brittle, and are liable to be broken Magnesium has a very definite and distinct characteristic when used for the pegging of bones It is absorbed within a few weeks, and in the process of its absorption it greatly stimulates the callus production and the ossification of the same Of the other forms of absorbable bone pegs Groves has not yet found any which give good results with animal experiments He has used decalcified bone, horn, catgut, gelatin hardened with formol, and fibrin round an axis of catgut Of these horn is the best, but in all cases the softening takes place too early, that is to say, before any organic fixation has occurred, and then complete displacement takes place

16 **Rashes in Puerperium.**—Byers is of the opinion that scarlatina is rarely encountered during the puerperium When it does occur during the puerperal period it is, as a rule, a mild disease, that is, with the use of modern aseptic and antiseptic precautions What has been called "puerperal scarlatina" is almost always a form of septic infection with a rash resembling the eruption seen in true scarlatina From a person ill of scarlatina there may be conveyed to a lying in woman either (a) A true scarlatina, or (b) septicemia, arising from the secondary septic changes which are apt to take place in the throat, etc, in scarlatina The former (a) occurrence seems to be rare, while the latter (b) should be avoided by modern aseptic and antiseptic precautions

22 **Early Case of Chorio Epithelioma Uteri.**—This case is chiefly of interest from the clinical point of view, being one in which a chorio-epitheliomatous uterus was successfully removed within five weeks of the passage of a hydatidiform mole Fourteen months later, the patient is alive and well, with nothing to suggest either recurrence or dissemination Microscopically the specimen was a typical chorionepithelioma malignum with a preponderance of cells of the intermediate type There was a striking preponderance in the tumor of intermediate or wandering cells, with a comparatively scanty formation of syncytium and Langhans' cells It is noted, however, that masses of the latter were found in some of the sinuses of the myometrium, and that this, according to Schmauch, is clear evidence of the malignancy of the growth Both ovaries were the seat of lutein cyst formation, a phe

nomenon which has frequently been observed in cases of chorionepithelioma and hydatidiform mole, and which is regarded by some observers as a possible etiologic factor

29 **Operative Treatment of Fractures.**—Some of the essential features of using plates are emphasized by Walton He says that in fixing the plate there are many errors to be guarded against, and although the means of avoiding these errors constitute the most elementary rules of carpentry or practical mechanics, they are not uncommonly made when these arts are applied to surgery, and are responsible for a considerable proportion of the poor results The rules to be observed are At least three screws must be inserted, preferably two on either side of the fracture If only one be used on either side the plate acts as a perfect hinge and allows the fragments to swing round The plate must be strong enough not to bend or crack The drill must be chosen to fit the screw, It should be as wide as the shank only, and not as wide as the thread The screws must be short and with the thread cut right up to the head, otherwise the threaded portion will pass through the compact bone and be loose in the medullary cavity the screw then acting only as a nail, which will be loose and the union thus unstable. The screw should simply be inserted until slight resistance to rotation is felt If the hole be correctly drilled the screw will then be firm home If rotated further, the thread of the screw or the bone will only be torn off and the screw thus lie loose in the hole

When wiring is resorted to, two loops at least must be used, and the ends firmly twisted together with forceps Here again there are several simple mechanical points which it is important to observe A slight groove should be cut for the wire to prevent it slipping It need not completely encircle the bone The loops of wire should be placed either at right angles to the shaft of the bone or somewhat obliquely, that is, in such a manner that they tend to be more parallel with the line of fracture, for the tendency of these fragments is to override one another owing to the contraction of the muscles With this obliquity such a movement would be associated with a closer approximation of the ends, while if placed with the obliquity in the opposite direction the fragments would readily separate and override In twisting the ends of the wire it is essential that the two pairs of forceps with which the ends of the wires are grasped be so held that each piece of wire makes the same angle with the vertical otherwise one wire will alone be twisted round the other Not only is the grip imperfect, but the twisted wire will also rotate on its long axis, and thus is almost certain to break

Instead of a wire the ingenious instrument of Lambotte can be used This is shaped like a piece of wire split in its long axis, so that on section it forms a semicircle On the circumference a screw thread is cut A loop is passed round the bone, and when the two ends are brought together so that their flattened surfaces are in apposition they together form a cylinder with a thread cut on its outer surface A nut can then be screwed over them and the loop thus tightened to any degree The ends can then be cut off level with the nut The general subject of operative treatment of fractures is considered in detail.

31 **Localized Intracorpuscular Sulphemoglobinemia**—The face of Davis' patient, a female, 27 years of age instead of being of the normal pink tint, was stained a deep slate blue almost a blue black This hue prevailed all over the face and scalp and over the exposed part of the neck, but it could not be observed anywhere else, except at the bases of the finger nails The bases of the toe-nails were of the normal color The mucous membranes were unstained On the face the color was most marked over the nose, but it was quite obvious in the sclerotics, the cheeks and forehead were also affected but the ears to a slightly less degree than other parts The color could not be dispersed by pressure Inquiry into the history of the patient elicited the fact that she had had measles when a child She had not had scarlet fever, pneumonia bronchitis rheumatism or chorea There was no history of the application of carbolic acid preparations or of the ingestion of silver compounds at any time Her face had assumed its present peculiar tint eleven years previously, at the age of 16 without any apparent cause and had not changed since that time Otherwise the patient was well and physical examination was negative

In blood taken from the ear the characteristic absorption band of sulphemoglobinemia in the red end of the spectrum was present A specimen from the finger was normal The two facts that the peculiar color of the skin is so definitely localized, and, further, that the spectroscopic characters of the blood vary according to the situation from which it is taken, combine to make this case, Davis believes, quite unique The depth of color varies considerably from time to time, almost from minute to minute Again, after having been out in the grounds for an hour or two on a rather chilly day the fingers in addition to the bed of the nails, have been seen to be obviously affected Lately, too, the pigmentation has shown a tendency to spread and it seems probable that the curious localization will disappear and that ultimately the discoloration will become obvious all over the body Simultaneously with the deepening of the color and its spread it is interesting to notice that the patient has complained of not feeling so well

33 **Vaccine Treatment of Pulmonary Tuberculosis.**—In certain selected cases of pulmonary tuberculosis, Hudson believes that a course of vaccine treatment is certainly of great benefit There is however, always a large amount of uncertainty, owing to the difficulty of isolating the causal organism, but even if the vaccine does no good it at any rate never seems to do any permanent damage, and therefore is always worth trying The treatment may be used in conjunction with tuberculin Hudson emphasizes that any injection or other treatment is only an adjunct, and that the general hygiene, open air, climatic and tonic treatment systematic rest and good feeling should be always strictly enforced

48 *Artificial Pleurisy in Treatment of Pulmonary Tuberculosis I Cecikas.
49 Recovery from Tuberculous Meningitis (Méningite tuberculeuse guerie) I Cottin

46 **Acute Forms of Tuberculosis**—Gougerot refers in particular to the form of acute tuberculosis characterized by the presence of tubercle bacilli in the blood and the absence of definite tubercle formation The clinical symptoms are those of typhoid, but the daily temperature variation is apt to be greater, the Widal reaction is negative, and there are no rose spots In case of typhoid without rose spots, this "typhobacillosis," as Landouzy calls it, should be suspected and the blood examined for tubercle bacilli and tested by animal inoculation

47 **Nitrogen Elimination in Tuberculosis**—Labbé and Vitry state that the total nitrogen excreted in the urine of tuberculous patients is lower than normal, it averages 8 gm in twenty four hours The urinary coefficient is lower than normal, which shows that more nitrogen than normal is being excreted in some other form than in urea This is verified by studying the purins and the ammonia which are both excreted in somewhat larger quantity than normal The increase in purins is accounted for by the fact that the abnormal destruction of the patient's own tissues sets free an increased amount of nucleins All these urinary findings increase in degree with the progress of the disease

48 **Artificial Pleurisy in Treatment of Pulmonary Tuberculosis.**—Cecikas reports two tuberculosis cases in which he produced artificial pleurisy by injection of turpentine, with resulting marked improvement in both instances He believes that the products of the inflammation thus elicited are antagonistic to the tubercle bacillus, and that the good results obtained with artificial pneumothorax are due to this cause and not to the compression of the lung

57 Case of Primary Chorionepithelioma of the Ovary (Zur Frage des Epithelioma chorioectodermale) R Klotz

53 **Genital and Peritoneal Tuberculosis**—Wolff gives ten four page tables showing the details of eighty two cases of genital or peritoneal tuberculosis in women In 68 3 per cent both the genital organs and peritoneum were involved In only 7 3 per cent were both oviducts alone the seat of the tuberculous process, and in 2 4 per cent one tube alone No instance was found of a tuberculous process in the ovaries alone, but this occurred in the uterus in 3 6 per cent Five of the eighty two were girls under 20 but most of the patients were between 20 and 35 Only 37 per cent of the total eighty two women had normal menstruation In thirty one cases the diagnosis had been erroneous In the fifty five operative cases, 75 per cent of the patients were living two years later and only 52 per cent of the twenty one treated by conservative measures alone, while only the mildest forms of the tuberculosis were given conservative treatment The final outcome with operative treatment is so satisfactory that it imposes the necessity for surgical measures in every well established case of genital or peritoneal tuberculosis in women The operative measures should be supplemented by the usual general ones, and Wolff agrees with Franqué that there is no sense in abstaining from the curative measures on the tuberculous pelvic organs just because this does not cure tuberculous processes elsewhere in the organism The operation relieves the patient from her local disturbances in the pelvis and thus accomplishes at one stroke what may require years under conservative measures if ever attainable by this means

56 **Rupture of Uterus after Cesarean Section.**—Wyss reports two cases of this mishap during a pregnancy following delivery by cesarean section, and compares them with forty two similar cases from the literature In eight cases on record the old cicatrix parted, in nine others a fistula developed, in three the abdominal walls ruptured, and in eight the cesarean section wound burst open a few days after it had been sutured In two other cases in Wyss' experience a woman died from paralysis of the bowel following the bursting open of the laparotomy wound The various experiences related emphasize the necessity for limiting cesarean section to the cases in which it is strictly needed, and, where it is indispensable, the necessity for applying at the same time some operative measure to prevent further conception After a woman has had cesarean section done, she should go to a maternity during the last weeks of following pregnancies so as to be under constant medical supervision

66 Serodiagnosis of Staphylococcus Disease G Wolfsohn
67 Technic for Obtaining Blood for Laboratory Examination W Lintz.
68 Nomenclature of Salts R Sodemann

60 **Principles for Successful Organotherapy**—Münzer comments on the well established fact that the ductless glands seem to work in pairs, one of each pair stimulating and the other checking certain functions By operative removal of the gland that does the checking, the stimulating gland is left in full control and the function of which it has charge receives only the stimulating activation The logical conclusion is therefore that before utilizing glands for organotherapy their antagonists should be removed He cites as an example Cushing's recent research on carbohydrate tolerance before and after removal or exclusion of the posterior lobe of the hypophysis cerebri His experiments all demonstrate that the posterior lobe has an inhibiting action on the oxidation of carbohydrates and is thus an antagonist to the pancreas which, we know, is concerned in this oxidation of carbohydrates For organotherapy, therefore, a pancreas should be used which has been previously activated by removal of its antagonist, the posterior lobe of the hypophysis Only in this way will organotherapy accomplish what has been hoped from it, and its use be extended

61 **Predisposition to Tuberculosis**—Hart discusses the constitutional and acquired factors liable to induce a predisposition to apical disease, especially the mechanical injury from lack of proportion between the anatomy and the functioning of the upper aperture of the thorax He lays special stress on the prophylactic influencing of the growing thorax in the young This would render Freund's chondrotomy unnecessary except in the cases of pure age ossification, here it is of great importance and benefit

63 **Flat-Foot with Intermittent Claudication**—Brandenstein reports three cases of this combination in men in the forties The disturbance from the flat foot had only been aggravated by insoles, as they impeded the circulation in the foot still more In these as in a number of other cases not reported here, great benefit followed application of measures to act on the circulation alone, superheated air, potassium iodid and heart tonics Objectively no modifications could be detected, but the patients were relieved of almost all their disturbances, even in the cases free from a history of syphilis The trouble in this combination of arteriosclerotic intermittent claudication and flat foot is generally attributed to the latter alone, and the more serious vascular affection is overlooked or regarded as of no moment, so Brandenstein lays special stress on the necessity for being on the lookout for it in persons with flat foot who are no longer young

October 20 XLII No 30 pp 1129 1176

69 *Exophthalmic Goiter (Morbus Basedow) A Oswald

69 **Nature of Exophthalmic Goiter**—Oswald presents a summary of what has been done recently in the line of research and theory on the subject of Basedow's disease and crystallizes out of it the conception that exophthalmic goiter is the result of both a thyroid and a nervous factor The thyroid secretion acts on both the sympathetic and the cerebrospinal nerve systems This has been abundantly proved by animal experimentation, to which Oswald has some unpublished experiences to contribute Increased secretion in the thyroid has no clinically appreciable injurious influence on the two nerve systems when they are sound But when one or the other of the two great nerve systems is irritable or diseased then the products of excessive thyroid functioning irritate the irritable nerve system If this happens to be the sympathetic nerve system then this in turn stimulates the thyroid and heart to extra functioning A vicious circle is thus set up, constantly aggravating the morbid conditions and we have the clinical picture of exophthalmic goiter If the thyroid gland is then removed this puts an end to this secondary retro active morbid influence magnifying the irritation from the original cause The sympathetic nerve system is thus freed from the multiplier of its irritation and it gradually grows less irritable under the rest and hygiene which are an essential adjuvant in operative treatment of exophthalmic goiter This conception of the nature of Basedow's disease explains why thyroid and iodin treatment do harm in this condition They both have an injurious influence on the nervous system the first directly the second indirectly Exophthalmic goiter developing after infectious diseases is due to the same mechanism, it does not occur except in persons with predisposed nervous systems Endemic goiter very rarely passes into the Basedow type the predisposition on the part of the nervous system seems to be exceptional in the regions where simple goiter is endemic Without the predisposition on the part of the nervous system it is impossible to elicit exophthalmic goiter by feeding thyroid extract None of the changes found in the goitrous thyroid is characteristic for the Basedow type The most recent development in the Basedow question is the cooperation of the thymus in the process Oswald regards the thymus as merely a further aggravating multiplier of the original morbid condition When there is a persisting thymus the individual is in double danger from his Basedow there is a general constitutional anomaly which manifests itself in the persisting large thymus and possibly hypertrophy of the lymphatic apparatus This indicates low resisting powers the organism is less resistant to internal and external injurious influences, especially those affecting the heart. Removal of the thymus by thus abolishing one of the multiplying factors helps to break up the vicious circle, and this alone has been known to cure the exophthalmic goiter in some cases He states that a large persisting thymus is always found in those who die of exophthalmic goiter or during operations on the thyroid

Deutsche medizinische Wochenschrift, Berlin

October 17, XXXVIII No 42 pp 1961 2008

70 *Dietetic Treatment of Polyuria (Ueber die Diätbehandlung des Diabetes insipidus und ähnlicher Polyurien) H Strauss
71 Nature of Tuberculin Reaction (Wesen der Tuberkulinreaktion) F Meyer and K [illegible] Schmitz.
72 *Heart Disturbances with Endemic Goiter (Die Herzstörungen bei endemischem Kropf) J Bauer
73 *Improved Apparatus for Recording Venous Pulse (Neuer Apparat zur Venenpulsaufnahme) Henkel
74 *Changes in the Pancreas with Alcoholism M [illegible]auer
75 *Changes in Urine with Albuminuria Induced by Position (Lordotische Albuminurie und Titrationsazidität des Urins) E Fränkel
76 *Analysis of the Urine (Zur Harnanalyse) I Bergell
77 Percussion in Diagnosis of Fracture of the Skull (Die perkutorische Diagnose von Schädelbrüchen) W Goebel
78 *Treatment of Traumatic Gangrene of Leg or Arm [illegible]
79 Scleroma in Prussia (Neue Skleromfälle aus Ostpreussen) [illegible] Gerber

70 **Dietetic Treatment of Polyuria**—Strauss has long been calling attention to a special feature of diabetes insipidus namely the inability of the kidneys to produce urine of a concentration corresponding to the intake of solids The kidney is able to eliminate the solid elements only by washing them out in an excessively large output of urine In doing this the tissues get dried out This explains the benefit from a salt poor diet in diabetes insipidus in some cases When restriction in the amount of salt in the food fails to influence the polyuria then the amount of fluid taken should be restricted at the same time Restriction of both salt and fluid is not necessary unless the salt poor diet alone fails to have the desired effect He comments on the excessive drinking of fluid in many cases of diabetes insipidus as a bad habit restriction of the intake of fluid has a good educational influence The thirst can be relieved sometimes with fruit or rinsing the mouth with cold water or by sipping a little lemonade or carbonated water The absence of phenomena on the part of the heart and the comparatively normal blood pressure show he says that diabetes insipidus is not [illegible] very serious The injury of the cardiovascular system from transporting such large amounts of fluid is not so severe as [illegible] believe The intake of fluid in the evening should be [illegible] to avoid the interference with sleep He thinks that the protein intake can be reduced to 60 or 70 g [illegible] a functional neuros[illegible] or ar[illegible] is [illegible] had better be avoided

72 **Heart Disturbances with Goiter**—Bauer writes from Innsbruck, where goiter is endemic, to say that heart disturbances with simple goiter are common there but they differ from the usual forms of goiter heart The main findings are an accidental systolic murmur, more pronounced over the pulmonary artery, an accentuated second sound and slight enlargement of the heart dulness toward the left The apex beat is normal, the pulse not accelerated and there is not much subjective disturbance He regards these heart findings as due to thyroid intoxication, and calls them the torpid form in contrast to Kraus' overexcitable type of thyroid heart

73 **Venous Pulse Curve**—Henkel has devised a little apparatus which consists of a stand with three legs holding on the vein the pad connected with the drum The three legs of the stand are of hollow rubber and are held firm on the skin by vacuum action, the air being pumped out of them with a rubber bulb The little tripod thus fits tight to the skin and moves with it, while the recording pad can be adjusted to determine the vein pulse without interfering with the arterial

74 **Changes in the Pancreas in Alcoholism**—Lissauer has found in twenty four cases of gin liver that the pancreas showed more or less similar changes His findings confirm those of Weichselbaum in twenty seven similar cases The importance of this gin pancreas" is evident in the development of diabetes mellitus in persons addicted to liquor

75 **Lordotic Albuminuria**—Fränkel examined twenty one children with spinal disease and found eight free from any trace of albuminuria, while it was evident in the others In twenty two other children with albuminuria he found only eight without some anomaly in the spine Among other points learned from this research is that the total acidity increased in the children with albuminuria induced by lordosis, unless the children had been given beforehand a dose of 4 gm sodium bicarbonate It is possible, he says, that the elimination of albumin in these cases is due to abnormal production of acid It might be wise to give an alkali occasionally in addition to hygiene and tonics to combat the constitutional weakness Some of the children were pale and restless and complained of headache—all improving under the alkali In one child the albuminuria followed a scarlet fever nephritis, this scarlatinal nephritis never showed any influence from the administration of the alkali

76 **Test for Nitrogen in the Urine**—Bergell gives the details of a technic which he has found very useful, simpler and more reliable than the Kjeldahl tests, for determination of the nitrogen in the urine A quartz test tube is required and in this the nitrogen is determined after calcining with calcium oxid

78 **Treatment of Impending Gangrene of Extremities**—Noesske reported in 1909 the excellent results of slitting the end of the finger down to the bone and applying a suction cup when the part was threatened with gangrene By this means the stagnating venous blood was drawn out of the tissues and the arterial blood streamed in to take its place, thus restoring the circulation and warding off further trouble Liek has applied the same principle in a number of cases, especially pedunculated flaps when gangrene seemed inevitable, but he never found it necessary to go to such extremes as the above, numerous minute incisions proving all that was necessary and healing without leaving disfigurement This was particularly evident in a recent case in which a young man had had his right ear sliced nearly off It was connected with only a bridge of skin 1 5 cm wide Liek sutured it in place but the ear was blue and cold until he made fifteen small incisions, both on the front and rear, radiating from the meatus Each incision was 3 or 5 mm long, at first they did not bleed but after a time drops of dark blood began to ooze out and the ear began to resume its natural tint Gangrene was thus warded off and the ear healed in place He did not apply the vacuum cup, and he thinks that even for the fingers these minute incisions might give equally good results as Noesske's single deep incision while there would be no resulting disfigurement or impairment of function Liek urges exarticulation of the fingers as giving better results than the deformed stump left after serious injury of a finger Working men are less incapacitated by being left with four fingers than with a stiff and contracted fifth finger after too zealous conservatism

87 Artificial Common Bile Duct (Experimentelle Versuche über künstliche Choledochusbildung durch einfaches Drainrohr) L Arnsperger and N Kimura

80 **Glass Blower's Tumor**—Narath comments on the errors in diagnosis of the tumor in the parotid gland which is an occupational affection in glass blowers In Liniger's case two physicians had ascribed the trouble to rupture of the buccal mucosa, but in this as in a personal case described and in all the others but one on record, there was no rupture, the air had merely forced its way through the outlet into the gland The chronically stretched duct and gland never return to normal conditions and the workman may thus be partially if not totally incapacitated for glass blowing unless some appliance can be worn which will compress from without the duct of Steno and thus prevent entrance of air during the blowing, or the condition can be corrected by an operation Narath exposed the duct and dug it out of its natural opening into the mouth, carrying it farther along to another point where he implanted the mouth of the duct in the mucosa This made the course of the duct slanting instead of direct, and a sort of valve action prevented entrance of air The new mouth of the duct finally grew up with cicatricial tissue, preventing the outflow of saliva A second operation was therefore necessary and Narath excised most of the parotid gland from without and thus put an end to the pneumatocele while sparing the muscles and nerves He was impressed with the efficiency of his adjuvant injection directly into the gland of a caustic solution It speedily destroyed the gland tissue and he thinks that direct injections of this kind through the natural outlet might be sufficient to cause the shriveling up of the gland without an operation There would, however, be danger of importing infection from the mouth with this treatment, and the preferable technic, he suggests, would be to bring the mouth of the duct out through the cheek and then, when the wounds had healed, to proceed to the obliteration of the parotid gland with injections of the caustic zinc chlorid He is waiting impatiently for an opportunity to try this method in the clinic after experimental research In conclusion he suggests that possibly mere ligation of the duct might prove effectual

81 **Surgery of the Heart.**—Wagner states that there are now 260 cases of operations on the heart on record with recovery of about 50 per cent of the patients The signs of injury of the heart from a stab or gunshot wound are the external wound, the abnormal murmurs, the spreading area of dulness, Rose's "heart tamponade" (strangulation of the heart from accumulation of blood in the pericardium), anemia and subjective phenomena such as precordial anguish, pain in the heart region, sense of oppression and dyspnea Roentgenoscopy is seldom practicable in a case of serious injury of the heart As the prospects are good for operative treatment up to the fourth hour, the importance of an early diagnosis is evident. But the most serious cases do not always present the severest symptoms In a personal case described all the signs pointed to a stab wound of the heart and it was exposed by an operation but the heart proved to be intact, although blood had accumulated in and around the pericardium The man would undoubt

edly have recovered without the operation, and the case would then have gone on record as "recovery from a stab wound of the heart under conservative measures alone," when in reality there had been no wound in the heart

85 **Anthrax.**—Heinemann has compiled 2,000 cases of malignant pustule and compares them with his own experience, his impression being that operative measures offer invariably the best prospects for a cure The operation must consist in the most thorough excision of the entire diseased area The assertions in regard to the harmfulness of this are based on false premises, only an incomplete operation can do harm, the complete can only benefit in the treatment of local anthrax The mortality in Koch's 1,473 cases was 38 8 per cent, but the statistics brought down to date give a mortality of 5 8 per cent in 2,255 cases The entire material is tabulated under various headings, with a full bibliography

93 Experimental Syphilis in Rabbits (Kaninchenimpfung mit Syphilitikerblut und Blutserum) Aumann

91 **Operative Treatment of Congenital Stenosis of the Pylorus.**—Rammstedt reports the successful application in two cases of Weber's technic for a partial plastic operation on the pylorus without opening the mucosa Both patients were young male infants and the results were highly satisfactory The serosa and the thick muscular ring are incised without disturbing the mucosa, the muscular ring gapes at once afterward, sufficient to correct the tendency to stenosis The muscular ring was found closely contracted, bloodless, and, once divided, it separated, widening the lumen sufficient for the desired purpose To make sure of this, however, Rammstedt sutured the incision in the first case, drawing the lips transverse, and suturing a wisp of omentum over the whole to protect the line of suture beneath The child vomited occasionally afterward and was a long time in convalescing In future Rammstedt intends to refrain from the transverse suture, being convinced that the slitting of the muscular ring answers the purpose fully This corrects the spasmodic contracture of the pylorus, the hypertrophy will not cause disturbance if the spasm is corrected This is rendered certain by the finding of a hypertrophied pylorus in children who have recovered from early stenosis of the pylorus and have died of intercurrent disease If the slit pylorus is left a little incontinent, this can be regarded as an advantage rather than the reverse He treated the other male infant in this way more recently merely slitting the muscular ring of the pylorus below the mucosa not attempting any suture afterward and the results were perfect The infant was completely relieved of all disturbances and never vomited after the operation but rapidly recuperated under appropriate dieting As the duodenum is atrophied in these cases from disuse and is not accustomed to receiving much chyme at a time it must be gradually trained to this after the operation For these reasons and the injury from the inanition, it is best not to defer the operation too long

119 **Iron in Muscle**—Ishida's material was that of sixty one autopsies in addition to animal experimentation In the cases where there was muscular atrophy, he was able to demonstrate michrochemically the presence of iron in the striated muscle fibers This iron did not come from blood pigment but from the muscle itself, probably from the so called muscle hemoglobin In animals the same condition could be produced artificially by nerve section The iron was more abundant in guinea pigs than in mice. The practical value of this discovery is *that we can no longer say that an iron containing pigment* is necessarily derived from the blood

128 **Pepsin in the Urine**—Tachau reports research which shows that the digestive ferments in the urine cannot be relied on as an index of stomach disease

129 **Syphilitic Families.**—Wolf here reports a second series of nine women with syphilis in the Heidelberg clinic for mental disease, mostly with progressive paralysis They were all married and some of their husbands remarried, so that the series includes twenty persons, only two were free from probable or certain syphilis The series is a continuation of similar research on a group of forty five persons (reviewed in The Journal, July 20, 1912, p 236) Of the sixty six pregnancies only thirty three viable children were born, and fourteen died in childhood, three committed suicide at 12, 20 and 28, two were epileptics, and one died after an abdominal operation, thirteen are still living but only two are normal The others are all feeble minded, epileptic, hysteric or with other nervous affections This research was not undertaken to show the frequency of syphilitic nervous disease, but it demonstrates the great share which syphilis has in the development of nervous affections The data presented show further that the assumption of a nervous predisposition is untenable, for the same parents in later years, after recovery from the syphilis, were able to generate healthy children The first series showed that "occult syphilis" generally runs a comparatively mild course to the end On the other hand, the second series show that the nervous form may prove an exceptionally serious taint for the family

130 **Hemophilia**—Gressot reports extremely minute clinical research for months in a case of hemophilia with necropsy two hours after death The findings show that a general lack of thrombokinase cannot be the cause of hemophilia, but it is certainly lacking in the blood It can be supplied from without in local application to the bleeding points in the form of fresh blood, serum or tissue juice By this means the flowing blood can be rapidly coagulated and, provided that the thrombokinase can get deep enough into the wound, *the hemorrhage may be* arrested by it This local application can be applied only to hemorrhage from the skin or mucosa of the mouth No other means proved effectual in controlling the hemorrhages in the case described, although all the measures in vogue were given most thorough trial There was no history of hemophilia in preceding generations, but the patient was the last of five brothers who had succumbed to bleeding from the gums or head after comparatively slight injury The patient has five sisters, three of whom are married and are normal and their daughters are also normal, but each has lost one or two sons from hemophilia

131 **By-Effects of Sodium Bicarbonate in Large Doses in Diabetes**—*Hanssen presents evidence to show that* while the bicarbonate may arrest coma in diabetes mellitus, yet this effect is only temporary The coma is merely postponed, and it is sure to return sooner or later The alkali has also a pronounced effect on the weight, probably from the following retention of water He tabulates fifteen cases in which the weight increased from 0 1 to 12 4 kilos (27 28 pounds) in from one to eleven days The details of eight coma cases are also tabulated with the necropsy findings Extreme hyperemia and edema in the meninges of the brain were found in every case, accompanied by hemorrhages in five cases In three of the six cases in which the sodium bicarbonate had been given intravenously, clonic or tonic spasms followed Albuminuria was a constant finding in all the severer cases of diabetes, but it regularly subsided under the alkali

133 **Intermittent Exophthalmic Goiter**—Curschmann calls attention to some cases in his practice in which the severe and complete picture of exophthalmic goiter developed at intervals, accompanied by other paroxysmal phenomena indicating disturbances in both the cerebrospinal and sympathetic nerve systems He has found only one reference in the literature (H Herz, 1902) to Basedow symptoms occurring intermittently in connection with vasomotor ataxia His first patient had tabes, and during his severe gastric crises all the symptoms of exophthalmic goiter developed in a pronounced form, the exophthalmos, tachycardia, sweating and tremor, and the thyroid swelled *At first all these symptoms subsided with the gastric* crisis without leaving a trace, but in time there was permanent persistence of slight exophthalmos and thyroid enlargement all the time, becoming exaggerated during the crises In his two other cases the intermittent Basedow accompanied attacks of asthma The exophthalmos, tachycardia, sweating and tremor were associated with various vasomotor symptoms, redness of the face and conjunctiva, cyanosis of the fingers, etc, and psychic disturbances, irritability, agitation, depression, etc., but the thyroid did not become enlarged One of the men had symmetrical lipomas in his neck, and these swelled notably during the attacks but subsided again afterward, confirming the assumption of a connection between lipomas and *thyroid functioning The same injurious influence* which induced the asthma and the thyroid intoxication, manifested in the intermittent Basedow, acted on the vasomotors of the lipomas The essential primal cause seems to be thus some irritation of the nerves regulating the secretion of the thyroid Curschmann's three cases of intermittent exophthalmic goiter throw light on the mechanism of the affection, and are further interesting from the therapeutic action displayed by epinephrin in regard to the tabetic crises He found that three to ten drops of the 1 1,000 solution, by the mouth, *arrested the crises* much sooner and more effectually than morphin and sodium

nitrate The epinephrin proved effectual also in arresting the asthma plus Basedow attacks in the other cases

134 The Parathyroids in Nephritis—In order to induce hyperfunctioning of the parathyroids, Georgopulos removed the thyroid in rabbits and then induced nephritis by injection of uranium nitrate. The results observed suggest that the parathyroids counteract the systemic intoxication in nephritis, and thus that an extract of these glands might prove useful in treatment of nephritis in man

136 Signs of Healed Tuberculosis—Goerdeler analyzes the necropsy findings in the lungs of persons known or suspected to have had tuberculous processes, and he devotes nearly one hundred pages and three colored plates to a discussion of the interpretation of the anatomic findings In the same lung there may be induration of both tuberculous and non tuberculous character and it is often extremely difficult to differentiate them This difficulty renders it impossible to decide with any certainty as to the actual prevalence of pulmonary tuberculosis among adults Many linear adhesions in the pleura and patches of induration in the apices have nothing to do with tuberculosis, and diffuse calcification and ossification are no criteria of tuberculosis The statistics showing tuberculosis in 100 per cent (Nägeli), 91 (Burkhardt), 80 (Harbitz), or 60 per cent (Beitzke), of the cadavers examined should be corrected to percentages approximating Goerdeler's own, namely, 59 3 per cent of 284 cadavers were certainly tuberculous, while 39 per cent. were probably or possibly tuberculous The behavior of the elastic fibers and deposits of carbon are instructive differential points

137 *Fracture of Patella (Zur Nachbehandlung von Patellarfrakturen mit totaler Zerreissung des Streckapparates). Gelinsky
138 Tibia Flap for Gap in Skull (Ersatz von Schädeldefekten aus der Tibia) Kleinschmidt.

137 Fracture of the Patella—Celinsky refers in particular to fracture accompanied by total laceration of the extensor apparatus The torn muscle retracts and shrivels and the longer this lasts the greater the force required to pull it out to unite the stumps again The operation should follow the injury as soon as possible, the next day at latest. Treatment should aim to suture the bone and muscles, relieve the traction on the sutures, and exercise the knee as soon as possible These requirements he has met with an adjustable splint holding the knee slightly flexed, the flexion can be increased at will by forcing the heel nearer the hip by turning a crank screw The screw thread is so fine that the heel can be moved part of a millimeter at a time This permits gentle stretching of the muscle, stopping at the least sensation of overtraction The muscle soon accustoms itself to the new position the tension subsides, and after fifteen minutes the screw can be turned again and the muscle thus stretched a trifle more At the close of the exercise the screw is wound the other way, bringing the heel back to its former position This can be repeated several times and thus gradually the muscles can be flexed and stretched keeping them in physiologic condition He gives the details of three cases in which he applied this method with complete recovery In one case carelessness resulted in the tearing through of the suture of the bone at the close of the first week An apparatus was then applied consisting of two claws fastened on each end of a rod with a screw thread The claws were inserted in the outer edges of the patella and screwed together on the rod until they held the parts of the patella in close coaptation In little more than a month the injured limb was ready to use at polo The three cases illustrate the slight dependence that can be placed on the suture of the bone The main thing is to restore normal conditions in the muscular apparatus When this is done if the parts of the patella separate later no harm results The claw apparatus described can take the place most effectually of suture of the bone, and in future Celinsky would not attempt the latter Another advantage of the claw apparatus is that it does away with muscular traction on the suture The claws can be left in place for three or four weeks The tips are anchored in the tendons and do not enter the joint proper An illustration is given also of this claw device

155 **Puerperal Fever and Fever in the Puerperium**—Brandt states that the science of medicine has been passing in the last ten years through a "mask and glove period" from which it is now emerging Masks and gloves have not proved effectual in warding off infection and science is returning to the old conception of the *vis medicatrix naturae*, or, as we call it now, the resisting powers of the organism He expatiates on the dangers of allowing the public to cherish its present belief that when there is fever in a maternity case the obstetrician or attendants are at fault Even certain physicians now cherish this belief, and it is not only erroneous but it may lead to disastrous consequences He presents an array of evidence to prove that fever in the puerperium is not necessarily puerperal fever It may be the manifestation of a perforating gastric or duodenal ulcer, appendicitis rupture of an old pus focus in the uterine adnexa, miliary tuberculosis, gonorrhea, infected extra genital thrombi or osteomyelitic focus The open wounds in the genital organs may become infected from some infectious process in the tonsils, from a mastitis or otitis media, while actual puerperal fever can certainly develop from self infection The diagnosis of actual puerperal fever cannot be made with certainty without direct visual inspection of the internal genitals at necropsy or an operation He gives the details of nine cases in which to the lay mind everything seemed to indicate puerperal infection, and yet this was absolutely not the case in most of them He urges the necessity for great caution in certifying to a death from puerperal fever when there has been no internal examination by the physician or attendant In the first case, during the puerperium there was subfebrile temperature and occasional coughing and an effusion developed in the right iliac fossa The respiration suffered and the patient died the twenty ninth day three days after the death of the child The temperature curve was not that of puerperal infection, and necropsy revealed an old left pulmonary tuberculous process, a right tuberculous salpingitis and miliary tuberculosis, and the child's lungs were full of tubercles Without the necropsy the death would have been credited to puerperal fever without fail In the second case the puerperium was normal but two weeks after the patient's return home, headache and high fever developed as the first signs of sepsis, fatal fourteen days later Necropsy here showed the uterus in normal involution, with nothing pathologic in the adnexa or surrounding tissue. Absolutely no cause for the infection could be discovered except a small ulceration on one toe If the temperature and pulse curves and the necropsy findings had not shown such a normal course, this would have been regarded as a tardy puerperal fever In a third case the woman had had placenta prævia two years before and she had "caught cold" before the present childbirth The temperature and pulse were normal after a slight rise the third day, ascribed to the mild coryza with herpes Otherwise the puerperium was normal and the woman was out of doors after her return home As she did not feel quite well, she called a physician who found nothing pathologic and merely advised repose As she continued to feel badly she called another physician who found then fever and an effusion near the uterus, and the woman died a month after dismissal from the hospital The physicians ascribed the death on the certificate to "puerperal fever of five weeks' duration" The husband instituted a suit for damages against the maternity, claiming that his wife had been dismissed while she had puerperal fever The maternity curves showing the normal temperature disproved part of this allegation There was no necropsy In this as well as in all the other cases reported no internal examination had been made by physician or attendant The most probable explanation of the case is that some pathologic process left from the old placenta prævia had flared up during the involution of the uterus after the patient was up and about, and parametritis had followed This case emphasizes anew the necessity for examining the maternity records and the post mortem findings before certifying to a death from puerperal fever In some of the other cases an intercurrent appendicitis or flaring up of an old process was responsible for the clinical picture of the puerperal fever In others the patients had inflammation of varicose veins in the legs before delivery, and the inflammation spread upward, entailing a three months' sickness Brandt considered the advisability of ligating the varicose vein but did not do this, in future he would ligate at once in such a case, striving to prevent the upward spread of the process in the femoral vein There is no question that many cases of embolism in the puerperium are due to old thrombophlebitis The genital organs undergoing involution offer a point of lesser resistance, so that infection from any point in the body is liable to localize there and get the physician or midwife into trouble unless the profession combats the present prevailing idea that fever in the puerperium is due inevitably to some sin of commission or omission on the part of the obstetrician or attendant

156 **Pregnancy and Other Intoxications**—Benestad groups beriberi, scorbutus and eclampsia together as affections due to products absorbed from the intestines or the glands with an internal secretion or from the fetus He theorizes to explain them all as the result of absorption of unfinished products Under normal conditions the products are elaborated a little more fully and are not toxic. In pathologic conditions, these products are unfinished and represent intermediary products which have a decidedly toxic action when absorbed. The manifestations are mostly nervous phenomena, cramps, convulsions and kidney or cardiovascular symptoms and hemorrhages The outcome as a rule is either death or complete restitution In all this group, from the standpoint of both therapeutics and prophylaxis, the diet is of primal importance

157 **Complicated Gall-Stone Cases.**—Borchgrevink reports a case of perforation of the gall bladder with circumscribed peritonitis, another of ileus following perforation of the gall bladder and a third case in which the common bile duct became occluded after cholecystectomy He discusses the literature on this subject of operative loss of continuity of the common bile duct and means to remedy it

ARTERIOSCLEROSIS *

THOMAS D COLEMAN A M, M D
Visiting Physician to the Augusta City and Lamar Hospitals
AUGUSTA, GA.

Arteriosclerosis is a penalty of our present civilization and is increasing in frequency so rapidly that any study or contribution leading to its better understanding is well worth while

For a profitable consideration of the subject, certain fundamental facts of the physics of the circulation and the maintenance of cell life must be recalled The proper nutrition of the different organs of the body is dependent not only on the functional activity of their own cells, but also on the vital activity of the cells making up the cardiovascular mechanism Not only must both cell elements remain structurally and functionally intact, but there must be a certain intravascular tension in the arteries, arterioles and capillaries

I believe no physiologist holds that tissue nutrition can be maintained in the absence of tension This neither negatives nor loses sight of the principle of osmosis, which, in this connection, might stand for chemical tension A concrete illustration of this may be found in the kidneys As long as they function normally, even excessive blood-pressure does not cause albumin to be forced through the epithelium lining the tubules in appreciable amount, it is only when the vital activity of the lining cells is interfered with through long-continued strain, toxins or irritants, that albumin and possibly blood appear in the urine Following and perhaps concomitant with this, connective-tissue changes take place, and the sclerotic condition develops

A point quite puzzling and one requiring much study is Why is sclerosis sometimes localized and sometimes general? As a working hypothesis it might be assumed (1) that there is a local defect either congenital or acquired, in the organ or organs involved, or (2) that the specific toxin has a selective influence which acts on the vasomotor or trophic centers, regulating the blood-supply and nutrition of the part involved the toxin or irritant acting on the vasomotor mechanism and secondarily on the cells lining the arterial and capillary systems and producing sclerotic changes in the vessels and throughout the areas supplied by them

Excessive muscular work, either general or local, may impair the integrity of the vascular mechanism Even in this case it is likely that toxins resulting from tissue destruction may be operating As to how these act beyond certain generalizations it is impossible at this time to determine with any degree of accuracy It has been conclusively shown that local sclerosis without marked sclerotic change in other parts, occurs in the vessels of the brain, and that to this condition is due the fact that so many more ruptures occur in this portion of the arteriocapillary tree than elsewhere but why? Is it because this portion of the organism is more actively employed during the entire cycle of life or because the vessels in this region are more vulnerable through constant use and grow old while the other parts of the body are yet young?

Certain it is that apoplexy is relatively frequent here while it is relatively infrequent in other organs irrespective of age The importance of this phase of the subject is apparent when one reviews the number of sudden deaths the frequent paralyses that make the further life of the sufferers a burden to themselves and the state — all the result of sclerosis not infrequently limited to the cerebral arteries If the preapoplectic symptoms could be interpreted with any degree of accuracy, how many of these tragedies of existence might be averted? Neither the trained tactile sense nor the sphygmomanometer is a sufficient danger-signal I have had the opportunity of being with a number of patients immediately before, during and after the rupture of cerebral vessels and beyond some increase in vascular tension and irritability of temper or depression of spirits there was nothing to give warning of the impending catastrophe

Again the vessels of the kidneys are especially liable to undergo sclerotic change producing commonly chronic interstitial nephritis In these cases also it is desirable to know why the local sclerosis of the renal vessels occurs at times without appreciable change elsewhere The liver vessels undergo sclerotic change and the same problems confront us from what we know of the functions of this important gland we should expect to find sclerosis more commonly present in it than the kidneys and yet I believe that this is not the case Sclerotic change may occur in any portion of the arterial tree and atheromatous patches are frequent in the larger trunks after middle life the coronary arteries being especially subject to sclerotic degeneration Coronary sclerosis alone has frequently been encountered

It may be maintained that all these organs are more or less constantly active and more liable to degenerative change It is not so clear however why the arteries of the extremities are prone to undergo sclerotic change for their activity is not so great or so constant as in the organs mentioned Yet sclerosis occurring in the arteries of the extremities and the head is common [illegible] it is in the former that we make [illegible] of the degree of the sclerosis [illegible] existing within the arter

---

* Read in the Section on Practice of Medicine of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912

ETIOLOGY

Admitting, then, that it is impossible at this time adequately to explain localized sclerosis, it is nevertheless profitable to inquire into its general causation, its method of manifestation and its course and management Age is a certain producer of sclerosis, but a fixed span of years cannot be given After middle life a certain degree of sclerosis is apt to be found in the majority of persons Though the expression be trite, nothing is truer than the axiom that "a man is as old as his arteries," some men of 40 years being in reality 60, 70 or 80 The life of an engine is dependent on the metal which goes into its construction and the care that is taken of it; the same is true of the more perfect physical mechanism, and Osler has aptly observed that a man often takes less care of his body than he does of his motor. It is undeniably true of the body as of the machine that it is better to wear out than to rust out, but in purposive design neither extreme is desirable

Aside from age, the unfailing producer of sclerosis, we have other causes operating, chief among these is the high pressure at which the human machine is run in our modern civilization The average man or woman lives in an atmosphere of work and worry, taking insufficient thought of either physical or mental needs One could follow up the myriad avenues of life indefinitely, but they all lead through ways more or less unwholesome and end in the one meeting-point, premature decay Man presents a pitiful spectacle racing at top speed to gain wealth or position, staggering under the delusion that old age will bring rest and enjoyment, and becoming enlightened, alas, too late, to find that his rest is disturbed by discomfort and that enjoyment is a memory only

In a practice of more than a score of years I have seen many instances of men who have slaved through life and gained their golden fleece, and who, if their bodies were not broken by ill health, found themselves so enslaved by the habit of work that rest was positive punishment Such men are like the old blind treadmill horse which, having earned its freedom, when turned out to pasture each morning as the sun rose, walked in a circle till the night

Next to the stress and strain of modern life, and undoubtedly augmented by it, come the acute infections and intoxications as causative agents These act as irritants to the cardiovascular apparatus, impairing the vitality of the cells forming their structure and inducing sclerotic change, which makes the vessels less elastic and interferes with the normal metabolism of the organism

Syphilis is a common producer of sclerosis, and I believe that, as our knowledge increases, it will be proved to be a much more frequent cause than is realized by our profession to-day

Next come poisons, under which may be included lead and other mineral poisons, alcohol, tobacco, tea, coffee, etc Billings has shown the causative rôle played by lead, and others believe that mercury when taken in large quantity and for a long time produces it Alcohol may be classed as an indirect causative agent, in that when used to excess it produces digestive disturbances, which in turn result in auto-intoxications, which are admittedly a prolific cause of the disease

It would be amiss if in this connection I did not cite Cabot's scholarly paper on alcohol as a producer of sclerosis in a long series of cases he found sclerosis much less frequent among a series of hard and chronic drinkers than among a similar series of professional men It should be borne in mind, however, that his work does not prove that alcohol does not indirectly produce sclerosis, it does prove that sclerosis is less frequent in alcoholics than in those who live constantly under high tension In this connection Osler calls attention to the fact that not infrequently persons who are abstemious in the use of alcohol are "exceedingly careless and indulgent in the matter of eating" Other authorities are equally suggestive on this score It is often the case that men who are innocent of one excess go to another Again, sclerosis is found in those whose occupations demand great and continued physical strain, and in young men who keep up high and long-continued tension in athletic sports

SYMPTOMS

The effect of arteriosclerosis, by whatever cause it may have been produced, is the disturbance of function, the parts involved become less active and atrophy more or less gradually, according to the speed of the circulation Sclerosis may involve only the smaller arteries, in which the symptoms will vary with the part or parts affected The first symptom may be sudden death from the rupture of a cerebral vessel or thrombosis of a coronary artery

In the kidneys the sclerotic change affects not only the vessels but the interstitial tissue and parenchyma of these organs as well, and is evidenced clinically by changes in the urine A common form of nephritis following sclerosis is the contracted kidney, in which the blood-pressure is usually high, the apex-beat of the heart is displaced downward and to the left, there is a "thudding first sound" and an accentuation of the second, and more or less nervous and digestive disturbance, with the appearance of albumin and casts in the urine

Sclerosis occurs in the splanchnic vessels, manifesting itself during life by irregular and otherwise unaccountable attacks of abdominal pain Advanced sclerosis of terminal larger vessels may result in necrosis or gangrene, and sclerosis of smaller ones, in hemorrhagic infarcts Finally, it must be borne in mind that sclerosis of the vessels of all the parts mentioned may occur without "any change in the palpable arteries" Since many of the symptoms of the early stages of the disease are indefinite, obscure and not pathognomonic, it is plain that its early diagnosis is at all times difficult and frequently impossible

It is this phase which makes the critical study of arteriosclerosis all the more imperative, for it is only in its beginnings, whatever be the etiology, that any hope of cure can be promised After sclerosis is well established a return to the normal should not be expected It is of the utmost importance, therefore, that the general practitioner be on the alert to discover the earliest recognizable symptoms These are left ventricular hypertrophy, digestive disturbances, more or less irritability of temper or other nervous phenomena, and the presence of albumin and usually casts in the urine, although cases may occur with any of these absent

The blood-pressure is estimated through the medium of the touch in palpable arteries and by the employment of an instrument of more or less precision, the sphygmomanometer This instrument should be more generally employed in all physical examinations, as its evidence is of no small value, it is, however, subject to considerable error and should not supplant the touch of the skilled examining finger If time permitted, it would be profitable to go into these defects in detail Hoover, in an excellent contribution to this subject, makes the following observations

> Whether there were really different endovascular pressures in the several arteries or different degrees of hypertonus in the arterial walls which gave the results, the deduction remains the same, namely, that the blood pressure apparatus applied to the accessible arteries does not give infallible information as to the aortic blood pressure, as a consequence it is not safe to rely on routine measurements from the area as a guide to the employment of the vasodilators in treating patients with a high arterial pressure I do not wish to discourage the blood pressure apparatus It is a very valuable instrument, but its chief value consists in teaching us how to palpate the arterial pulse No instrument can take the place of the finger, nor can any instrument teach us so much about the pulse as can be learned by palpation

Daland has shown that the mere application of the pneumatic cuff in certain neurotic subjects often increases the blood-pressure as much as 30 or 40 mm

PREVENTION AND TREATMENT

The widest field for good lies in the prevention rather than in the cure of arteriosclerosis All causes which we know operate to produce the condition should be curtailed or eliminated as far as possible There are two parties in this problem, the physician as the educator, and the individual who is willing as far as may be to profit by the advice The individual should as closely as he can approximate the normal life, and excesses of all kinds, mental as well as physical, should be avoided The pace that kills and the strenuous life should be shunned Food should be taken in sufficient quantity, and of a quality calculated to maintain the body in a state of physiologic equilibrium, beyond this it is unwise to go constantly or at frequent intervals Alcohol, coffee, tea and tobacco should be used moderately, if at all

The exciting cause must be treated in sufferers from toxic agents in the blood, such as lead-poisoning, diabetes mellitus, syphilis, tuberculosis, gout, rheumatism and the acute infections It goes without saying that the age and general condition of the patient should be considered What would be moderate in the young would be immoderate in old age, we should not put new wine into old bottles

The treatment of arteriosclerosis may conveniently be divided into hygienic, dietetic and medicinal

Everyone requires a certain amount of exercise, the kind and amount should be adjusted to meet the demands of the individual When active exercise for one reason or another cannot be taken, much good will come from massage properly applied It quickens the circulation and increases the elimination of waste products In dilating the vessels of the skin, it to that extent diminishes the work of the heart

Baths properly administered are of distinct value, including hot baths hot packs, vapor-baths, tepid baths and carbon dioxid or the so-called Nauheim baths Cold baths are rarely indicated All have for their object the increase of blood through the skin, and also excretion by the skin, thereby diminishing the work of the heart and of the kidneys

The physical and mental activities of the patient must be carefully directed In some cases curtailment alone is sufficient in others total abstinence from all work, physical and mental is imperative It is frequently surprising to see the good that immediately follows after the patient has made a complete surrender in this direction Many an old boiler will last for years when run under diminished pressure

Time will not admit of going into the matter of diet in detail suffice it to say that the individual capacity will have to be studied in each case It is a fact that the majority of persons eat too much and nearly all too rapidly In mild cases cutting down the diet may be sufficient eliminating such articles as are apt to overburden the alimentary tract and the kidneys In general, meat should be indulged in sparingly The sugars may be borne well by some but are apt to lead to gastro intestinal fermentation Milk, variously modified eggs, fresh vegetables and fruit are more or less staple articles, as is bread, and may be taken by most patients In advanced cases a rigidly restricted diet is at all times imperative In all cases the amount of alcohol tobacco tea and coffee allowed should be moderate and doubtless the best rule in many cases is "not at all Since we have seen, however, that a large degree of sclerosis is present in most persons after middle life it is not wise or expedient to be extreme in these matters until our knowledge becomes more exact

Individual instances often shatter one s theories I have seen men, in apparently robust health and advanced in age, who had throughout their adult lives been hard drinkers excessive users of tobacco, or immoderate tea and coffee habitues and yet sclerosis in them was in abeyance The total abolition of these creature comforts is often unwise and their regulation must be left to the wisdom of the physician

As to the use of mercury in syphilis, I should be willing to run the risk of producing arteriosclerosis by the use of mercury rather than to run the surer risk of having the sclerosis develop from the effects of syphilitic infection In all luetic cases the iodids are of value, and in many cases which are not luetic their rôle is distinctly good Their employment may be more or less empirical, but in a large number of cases I believe they tend to hold down tension and discourage sclerotic change

Nitroglycerin acts quickly and may be employed for a long time without harm, its chief drawback being its evanescence It rapidly causes dilatation of the peripheral vessels and if pushed sufficiently far will cause flushing of the face and headache It not only relieves the overburdened heart, but increases the activity of the kidneys It may be administered in appropriate cases in doses of from 1/50 to 1/100 grain every two or three hours for long periods without injurious effect Nitrite of amyl pearls may be broken and inhaled in urgent cases but are not a substitute for nitroglycerin The more lasting effects of the nitrites make them preferable, of these sodium nitrite in 1 grain to 3 grain doses repeated three times a day or every four hours, may be given

---

ABSTRACT OF DISCUSSION

Dr Louis Faugeres Bishop New York I believe that the causes of arteriosclerosis can be divided into two classes one in which the affection is due to certain poisons like lead and possibly other metals to syphilis and other infectious diseases, and a larger class in which the arteriosclerosis is compensatory Ninety out of 100 cases of high blood pressure are due to auto intoxication or to the circulation in the blood of amino acids which are produced by the breaking up of proteids in the intestinal canal and a failure on the part of the liver to exclude these toxic substances from the circulation I think that the high blood pressure is caused by an attempt on the part of Nature to force out of the system through the kidneys the products of protein decomposition and that the heart is damaged [illegible] kidneys My observations are founded on t[illegible] urinary analyses among th[illegible] York City A study of t[illegible] better picture of the cau[illegible] can get in hospital ca[illegible] restricted diet are misleading. Observation of the urine, covering a series of years, shows first an excess of indican, later one finds as well a faint trace of albumin and casts. As the case goes on the patient develops neurasthenic symptoms and then arteriosclerosis. I have followed many of these cases in private practice and I have come to certain definite conclusions. Arteriosclerosis is a very common affection among physicians. I have on my records sixty-five physicians with arteriosclerosis and in nearly every instance there was indican in the urine, a high blood-pressure, albumin and casts, and other features pointing to amino-acid poisoning.

The important point regarding these cases of arteriosclerosis is, of course, the treatment. Are the amino-acids coming from meat decomposition always the cause of the trouble? I do not believe that this is the cause in every case. Among the other possible causes may be overindulgence in eggs or fish.

Another very important thing in the treatment of these cases, I believe, is the proper administration of castor oil; these patients on beginning treatment are given 1 ounce of the oil for three days, then the same amount once a week and then the same amount once a month; the results obtained are often surprising. A third important measure in the treatment of these cases is physical labor. I have seen patients with arteriosclerosis who have had slight strokes of paralysis, with a blood-pressure of 230, and who, under the regimen mentioned in regard to the proteid diet and with the employment of physical exercise, have gone on for years.

DR. G. W. McCASKEY, Fort Wayne, Ind.: There are three factors to be considered in every case of so-called arteriosclerosis: First, the sclerotic changes in the blood-vessels proper; second, the cardiac sclerosis, and third, the factor which is clinically most important, because most amenable to treatment, the arterial spasm. So far as the etiology of arteriosclerosis is concerned, I think that two distinct causes should be recognized, the first being toxic, and the second mechanical and due to physical overstrain from various causes. The toxic causes may be derived from the intestines or may be the result of metabolic disturbances of one source or another, perhaps various products of the amino-acids. Severe physical strain or the overexcitement of the cardiovascular apparatus resulting from emotional excitement or mental stress undoubtedly produces arteriosclerosis.

It is important that we should have clear-cut notions of the therapeutic indications in these cases. We ought, in other words, to distinguish clearly between the organic changes of the blood-vessels and heart which cannot be removed, and the arterial spasms which are very largely removable. Rest in bed with thorough elimination, carefully regulated diet, from which the purin bodies should be largely if not completely removed, and the use of vasodilators constitute the proper treatment.

As vasodilators I commonly use the spirits of glonoin, and begin in hospital cases with 1 drop every hour, increasing every day or every alternating day to 2 drops per hour and pushing the dose in this way up to the limit of tolerance, or until satisfactory results have been obtained.

DR. HENRY O. MARCY, Boston: Arteriosclerosis is largely the result of the undue pressure that is brought to bear on the human machine which we should all learn how to care for and protect. To me the wonder is that the modern business man in our large cities does not break down earlier. In the whirl of business care, his every activity is in high tension. He takes little time for meals, pampers his appetite with every delicacy, uses coffee and alcoholic stimulants freely, smokes excessively, exercises little, sleeps badly and wakes to repeat the round. Over such a man at home the physician has little control. Send him to Carlsbad and note the change. Diet simple, largely milk, the waters in sufficient quantity to act on the excretory organs, no alcohol, no tobacco, nothing except as ordered by the physician. The psychotherapeutic effect of his hours of hot mud baths and repose four or five thousand miles from his business cares renovate him and make him enthusiastic over his cure, but he returns only to plunge again into the same round of business dissipation which leads to physical ruin. Why call the results by such meaningless names as "arteriosclerosis"? The duty of the physician is to sound the danger signal before it is too late, to teach hygienic living, abstemious habits, the simple life. We of the profession know that under wise guidance the ills of life would be reduced one half, the production of the race doubled and longevity increased at least one third.

DR. JAMES M. ANDERS, Philadelphia: Dr. Coleman spoke particularly of the localized variety of arteriosclerosis and of the great difficulty in finding its precise cause. I think that the majority of authorities are agreed that it is due most commonly to syphilis, and this also accords with my own personal experience and observation. To my mind the treatment or management of arteriosclerosis often savors of a comedy of errors. If the modern conception of the histologic changes of the condition be correct, if, primarily, the media is the seat of either productive or degenerative lesions, and to compensate these changes, the intima becomes greatly thickened, then surely, two things must follow: First, the lumen of the vessel must be narrowed, and second, the tension in the vessels must be raised to a corresponding degree. One is tempted to ask, Why attempt to interfere with this compensatory mechanism of Nature? I believe that the trend of the profession has been and still is in the direction of interfering too much rather than too little with this wise conservative process. There is, however, a class of cases made up of instances of incipient arteriosclerosis, in which the blood-pressure is considerably elevated, associated with a marked vasoconstriction due largely to nervous causes. Here absolute bodily and mental rest, arterial relaxants and liberal feeding will often effect an apparent cure, provided that the causes, both near and remote, can be successfully combated. It should not be forgotten that the principal aim in all cases must be to ascertain and then to combat causes.

DR. DELANCEY ROCHESTER, Buffalo, N. Y.: If anything was brought out clearly in the previous discussion of this subject in this Section several years ago, it was that the chief etiologic factors of arteriosclerosis are syphilis and hard work. Under the circumstances, to place these people at hard work is decidedly contra-indicated. Any exercise should be undertaken only under careful observation. I agree with what has been said regarding the reduction of the proteids in the diet, especially if there is a decided impairment of renal function. Elimination of waste products is of value in the treatment of this disease. I agree with Dr. Anders that arteriosclerosis, when localized, is largely a condition due to syphilis. Since the use of the Wassermann reaction we have found more evidence of syphilis as an etiologic factor in arteriosclerosis and changes in the circulatory apparatus, especially of heart and aorta, than ever before.

DR. M. A. COHN, Brooklyn: I wish to cite a case just now under my care. A man, aged 27, presented himself April 2, 1912, with the following history: While walking in the street with a friend twelve days previously he suddenly collapsed and was picked up unconscious and limp and pronounced dead, being refused admittance into the offices of two successive nearby physicians on that ground. The third physician finally allowed the dying man to be stretched on the floor while a hypodermic was being administered and the ambulance telephoned for. After remaining in the hospital one week, the patient was discharged as cured and was permitted to walk home without any warnings or restriction whatever. The man, a plumber by trade, big and well nourished, looked sallow and anxious, with dark rings under his eyes and he breathed rather laboriously. A careful examination revealed the following condition: pulse high tensioned, mitral and aortic systole feeble and muffled, the characteristic blue line about his gums, traces of albumin, some hyaline casts and a slight excess of indican in the urine, and some moist râles at the base of the left lung. On applying my sphygmomanometer, I was not a little amazed to find that no less than a pressure of 280 mm. Hg was required to stop the radial pulse. As a luetic history was positively denied and no signs or symptoms pointed in that direction, the conclusion was reached that the case was one of chronic plumbism producing arteriosclerosis and interstitial nephritis, the feeble myocardium giving rise to the pulmonary edema and to the frothy, pink expectoration which occurred the night prior to the patient's sudden collapse and continued for two days thereafter He was informed of the extreme gravity of his condition, was put to bed on a strictly milk diet, and, after a thorough elimination by bowels, kidneys and skin, was given potassium iodid to remove the lead from the system, doses of nitroglycerin were gradually increased Seeing, however, no improvement, subjective or objective, even after doses of 1/20 grain of nitroglycerin three times a day, I discontinued its use and on the suggestion of Dr G R Butler, who saw the case with me, began the use of ½ grain doses of erythrol tetronitrate three times a day with the simultaneous administration of 5 drops of the tincture of strophanthus three and four times daily and also short steam baths, with patient in bed, once every one or two days for a week or so The patient is temporarily improving, is allowed some outdoor exercise and a little more liberal diet, with little fluid, however The blood pressure is still above 240 mm, some albumin and casts are still to be found in the urine, but there were no attacks of angina pectoris recently, no dyspnea or polyuria and the whole of the Stokes Adams' syndrome is absent

Dr. Marvin L Graves, Galveston, Tex Until we know more regarding the etiologic factors concerned in the production of arteriosclerosis we can do but little in combating it A great deal of consideration should be given to the character of the life of the individual in ascertaining its relation to high blood pressure or arteriosclerosis Dr Bishop believes that these arteriosclerotic patients with high blood pressure should be urged to take exercise, but I think a discriminating judgment is absolutely necessary in treating these patients For instance, arteriosclerosis occurring in a laboring man who has been at active physical exercises all his life should be treated differently from that in a man who has been leading a sedentary life Under many conditions I do not think it would be advisable to prescribe large amounts of physical exercise for these patients who are afflicted with arteriosclerosis To order a man who leads a sedentary life, and who eats too much of all kinds of foods, not only the proteid foods but all kinds, to take physical exercise indiscriminately would tend only to work harm Such men should be kept as much as possible in the open air with properly graduated exercise, the total amount of food they were in the habit of consuming should be cut down, especially the proteids In doing this, many of these individuals would be relieved I think that a sharp distinction should be drawn between toxic conditions which produce high blood pressures and changes in the arteries which cause arteriosclerosis with its increased blood pressure

Too much stress is laid on the reduction of the blood pressure I have seen, in patients of 45 and 60 years of age, an unduly high blood pressure—one of 150, one of 200 or even one of 225 mm. Hg—which has been reduced by the enforcement of a rigid diet and the use of nitroglycerin or sodium nitrite, as well as an active purgation, under such treatment one also sees patients who are made worse and not better I do not believe that we should always try to reduce the blood pressure to what we consider to be the normal It is impossible, in my opinion to reduce to the normal with safety to the patient a high blood pressure which has been maintained for a number of years, especially with arteriosclerosis

Dr Tom A Williams, Washington D C Arteriosclerosis is a condition which can be prevented but which when it has occurred cannot be cured Many of the early symptoms are cerebral The guide in the treatment of individuals afflicted with arteriosclerosis should not be what could be accomplished in lowering the blood pressure *per se* but the study of the state and condition of the individual which determined his optimum pressure Naturally with a very high optimum pressure time of life will be short Of the means of treatment at our disposal the most important relates to the diet I believe in a diet which is similar to the Chittenden standard, that is that 50 gm protein per day is ample and should not be exceeded in these cases It is wonderful how well these patients will do when the proteins are cut down and more especially the proteins that are taken at the evening meal before the lowered oxidation of sleep Beyond abundance of succulent fruits and vegetables I do not believe that purgatives should be resorted to as eliminants They interfere with osmosis and muscle tone of the bowels and hence favor the absorption of substances which make for increased blood pressure Both as revulsants and eliminants I favor the use of hot baths and massage, and no expensive apparatus is needed The efficacy of active exercise in these cases is exaggerated but not contra indicated in those cases of arteriosclerosis which might be described as being in the presclerotic stage It is a very important thing for the patients themselves to appreciate their condition What is impending unless forestalled should be impressed on them by the physician in order that they may readjust their lives and do what is best for their greatest efficiency in the long run, even though it might result in some immediate loss of comfort or money These principles of practices have been of great value in my hands and have made unnecessary recourse to expensive measures like d Arsonval currents, water cures and the like

THE MENACE TO THE YOUNG CHILD OF THE COMMON INFECTIOUS COLD *

THOMAS S SOUTHWORTH, MD
NEW YORK

Many of my colleagues are doubtless convinced of the truth contained in my title, and would accept the text without the discourse which follows, for it is scarcely possible that my individual experience has been exceptional or that it has not been duplicated by scores of others Nevertheless, it has seemed to me proper to put my views in concrete form in the hope that there may result a wider realization and discussion of this problem in all its bearings

The observations of recent years have taught me to respect the common infectious cold as a far from trivial affection and one capable of inflicting serious injuries on its victims Ever since the initial intensity of the influenza pandemic of 1889-90 waned we have experienced recurring waves of infectious catarrhal colds which have been spoken of generically as influenza or grip or simply as colds In the absence of laboratory confirmation of the exact bacterial cause the classification of such endemic or epidemic affections has not been possible, and the resulting uncertainty has found expression in the loose terminology adopted alike by the medical profession and by the laity

Mention should properly be made in this connection of the careful work in this country by Wollstein but since her researches demonstrated the presence of the Pfeiffer bacillus as a causative or complicating factor in only a certain proportion of the inflammations of the respiratory tract among the infants studied they threw but little light on the etiology of the case under discussion save by indicating that such cases may be due to several diverse forms of microorganisms Nevertheless since it is well-nigh impossible under the ordinary conditions of general practice to differentiate true influenza from its imitators and since clinical observation has demonstrated the unmistakable infectiousness of such colds we are forced to consider them as a whole for the very practical purpose of inquiring whether such damage, especially among young infants, is not wrought by them which could be prevented by rational prophylactic measures.

---

* Read in the Section on Diseases of Children of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912

To these infections of the mucous membranes the infant seems to be especially susceptible. When one of these colds invades a household, several of its members usually contract it. While some adults may escape, the majority of physicians will bear me out that the baby or the child of runabout age is almost invariably affected. To such an extent is this true that nowadays when called to see a young child with catarrhal symptoms, I seldom inquire how the patient "caught cold," in the old sense of exposure to draughts or the elements, but ask at once whether other members of the family or household servants have recently had similar symptoms. I am seldom disappointed in my quest.

These infections spread rapidly and with great certainty through the wards of institutions caring for young children. During recent winters in one institution the morbidity from this source has far exceeded that from all other infectious diseases of childhood. As might be expected with children of the institution class, acute otitis media has been very common, pneumonia, less so though not infrequent, while acute suppurative adenitis, considered one of the complications of influenza, has been rare.

Serious as these recognized forms of sequelae are, there is yet another direction in which still more frequent and often irretrievable damage follows in the path of these infectious colds. I refer to their influence on nutrition. This is of somewhat less importance among children of the runabout age, but in any group of bottle-fed infants such infection not only prevents gain but is as a rule, accompanied by definite loss in weight. We are too prone to look on these colds as local affections when they are, in reality, systemic infections. If accompanied by fever, the former strength of the feedings must necessarily be cut down to avoid disturbances which would be caused by formulas which but a short time before the infant tolerated and absorbed. Even when there is but little fever the margin between tolerance and intolerance, ever narrow in such infants, is no longer sustained — gains cease and the weights go down. It has been my experience that whether the loss is caused by the necessary curtailment of nourishment or by the direct demands of the malady on the tissues, or by a frank disordering of the powers of digestion and assimilation the end-result is often the same, namely, the demolition of our carefully constructed edifice of nutrition and a renewed state of malnutrition from which some of the infants may not again be able to rally.

The experience of the ward, to which I first alluded because it is more striking from the number of infants involved, is also duplicated to some extent in private practice. Fortunately we have here to deal with fewer infants suffering from prolonged malnutrition, and even these have, as a rule, the advantage of a more favorable environment. Nevertheless, in conducting any case of difficult feeding in private practice that which we fear most is an intercurrent infection. Excluding the infections of the gastro-intestinal tract, which, if we hold to the former teaching, are largely limited to the hot and humid months, the infant in the home is, as a rule, fairly carefully guarded against the common eruptive diseases of childhood as well as against diphtheria and mumps, since the dangers of such maladies are well understood by the laity.

Not so, however, with the common infectious cold, which, with the sole exception of the regulation of the infant's food, calls more frequently in the winter for the attendance of the children's physician than any other condition or malady. Such colds are an unfortunate handicap in conducting feeding cases in private practice. The outspoken cases with fever are, of course, quickly recognized, but even when they yield promptly to treatment they interrupt the progress of nutrition. When complications ensue, this interruption is often prolonged. Where the cases are subacute, the effects are not generally recognized by the parents. In reviewing the history of an infant showing recent stationary weight, direct inquiries often bring out the fact that the infant has had a cold, the more immediate evidences of which may have largely disappeared. Guided solely by the stationary or downward trend of the weight curve, the food of such infants has often been increased by the mother or nurse, thus precipitating or increasing digestive troubles.

When a group of children in a family becomes infected, we often see established a house infection with, at intervals, recurrent outbreaks, which may extend over a number of months, until the advent of warm weather or the departure of the family to the country. The etiology of these recurrences is not clear. The presence of bacillus-carriers may be readily suspected, but against this theory is the comparative freedom during the summer months, only to be followed by a fresh outbreak of colds as soon as the children return to the city. This experience is so general in New York as to be a matter of common report among parents. Some susceptible children are kept free only by continued residence in the country, but unfortunately suburban colonies and country towns have their own share of infectious epidemics. Nor would I imply that such epidemics are limited to the distinctly cold months. For several years past, sharply infectious colds have appeared at the seashore resorts not later than August, and have been carried thence to the mountains early in September.

The amount of injury done young children each year by such colds can scarcely be estimated. Medical literature contains frequent references to the more recently recognized involvements of the accessory sinuses. Aural complications are so frequent that it is to-day a positive relief when called to see a child with rise of temperature and catarrhal symptoms, particularly if the temperature has been persistent, to find the ears normal and to be able to reassure the mother that the necessity for the otologist, single or double paracentesis, prolonged aural irrigations and a possible mastoid operation is, for the present at least, excluded by the findings. Fortunate indeed is the family containing children, one or more of whom have not suffered from acute otitis media requiring paracentesis.

During the prevalence of such colds, the possibilities of infection are excellent if the young child travels by train, rides in public conveyances or is taken to hotels or crowded shops. Numerous regrettable occurrences have been known to me in which disregard of these dangers has led to serious consequences. One instance, which will suffice, was that of an only child, aged 3, previously well, who was brought to the city for the sole purpose of seeing the Christmas display of toys in one of the large shops. This trip was immediately succeeded by coryza, followed by double otitis, double mastoid operation, and finally, sinus thrombosis. The child finally recovered but paid a large price for a few minutes of unnecessary indulgence.

Children's parties and dancing-schools for the very young come under the same ban It is indeed an open question whether the greatly increased opportunity for major and minor infections where young children are gathered together in kindergartens does not more than offset the real advantages which they offer If we exclude exceptional cases in which the discipline or companionship of the home is deficient, I am of the opinion that safeguarding the health of the young child is the more important consideration, and that any home worthy of the name should be able to furnish all the simple instruction and direction of the play instinct which the young child requires

Assuming that the young child is not subjected to exposure outside the home, there still remains the problem of safeguarding it from infection within the home Measures which will produce this result are, I know, not practicable in the crowded tenement, nor in those ranks of society where limited means and unfavorable environment make it imperative that the baby or other young children be closely identified with the family circle and inhabit the same rooms Nevertheless, there are an increasing number of households in our land where the infant or young child has, or may have if need be, its own room and its own attendant In homes where its welfare is considered paramount, and where neither expense nor personal inconvenience would be allowed to stand in the way, protection of the infant can be secured

The first requisite is a clear understanding by the parent of the direct and indirect dangers from exposure Isolation and quarantine of the affected adult member of a household is not always feasible unless the attack is sufficiently severe to confine the patient to bed Even then the period of convalescence usually renders such measures ineffective On the other hand, isolation and quarantine of the uninfected infant against the family and the majority of the household, although involving some difficulties is not impracticable Indeed the quarantine of the patient is regularly carried out when circumstances are thought to warrant it, as in diphtheria, scarlet fever and measles It is even willingly enforced for mumps and chicken-pox, because the visible brand of these maladies and the traditional dread of such conventional types of infection instantly suggest such measures Yet neither of these two latter affections produces a fraction of the harm wrought by the infectious colds

In addition to a recognition of the sinister possibilities of what often seem harmless infections the isolation of the infant calls more for unselfishness on the part of the parents than for anything else This means that at such times the parent or parents should be willing, if necessary for the welfare of the child to sacrifice their own pleasure in seeing it and playing with it As a principle, this seems simple but it is often the crux of the difficulty in putting such isolation into practice It is also extremely difficult to secure the immediate and complete isolation as a matter of routine of any child in a family of children when it first shows slight symptoms or beginning illness yet by such means I have repeatedly carried young children through house epidemics without their contracting the infection, and thus without interruption of normal growth and well-being

No discussion of this subject would be complete without mention of the occasional causes of infection foremost among which is the introduction of the casual visitor into the nursery Why a coughing or sneezing person should insist on seeing the baby or the maternal pride of the mother lead her to introduce her child into such an atmosphere in the drawing-room passes my understanding unless it be ascribed to sheer thoughtlessness on the one hand and untutored ignorance on the other

It is a comparatively simple matter for the physician to acquaint the mother with the risks incurred and to issue orders that no employee or member of the family having the slightest cold shall enter the nursery and that the direct question shall be put to any visitors before they are admitted With such clear instructions many possibilities are averted the education of the community is furthered and the immediate responsibility is lifted from the shoulders of the physician

It requires at least a decade to secure the acceptance of any new measures by a majority of the medical profession and another to make them the common knowledge of the laity I know of no text-book which as yet teaches the danger of the common infectious cold no medical school in which it is impressed on the student no hospital in which such cases are not retained in the common ward no health board which has yet dared to limit the right of the individual to spread the infection of his coryza among the public These may exist unknown to me, and the convictions to which I can lay no claim of priority will in time make themselves felt in these directions

I do know of enlightened private schools to which parents are instructed not to send their children if catarrhal symptoms develop but in some of these this appears to be more from the fear that such symptoms may be the beginning of measles than from any other reason Few other schools exclude the child unless the cold is well marked and attended by other evidences of illness It is true that the younger the child the more serious as a rule, are the results of such colds, but they do not fail to take their toll from children of school age, as the family physician and the aurist will bear witness

Only recently have we begun to appreciate the ravages of these subtle forms of infection With such knowledge, however goes the moral obligation to throw off our indifference, to face the question fairly, and to do all in our power to lessen the unnecessary morbidity and the too frequent pneumonia, otitis and lingering sinus infection

807 Madison Avenue

ABSTRACT OF DISCUSSION

Dr David E. English Summit N J Certain cases of common cold are due to infection by the *Bacillus influenzae* These are the cases that present great prostration afterward The toxins secreted or produced by the influenza bacilli seriously affect the heart I think that prolonged prostration which follows the common cold is proof that that common cold was due to infection by influenza bacilli In these prolonged prostrations I have found only two drugs that do good One, strange to say, is iron The other is sodium and caffein benzoate I do not mean the mixture in the Pharmacopeia but the combined salt made by Merck So far as I know he is the only manufacturer who makes it In moderate doses every four hours I have found this a great help in assisting children over this prostration The dose is based on a 5 grain dose for an adult Of course prophylactic treatment is fresh air and sunshine Babies who get enough fresh air are not usually affected

Dr. John Zahorsky St Louis Next to the nutritive disturbances are the acute respiratory diseases More than ten years ago I read before a local society in St Louis a paper on the etiology of colds and acute infectious diseases I insisted that all acute diseases of the respiratory tube in the young baby and young child are not due to cold or exposure but to germs caught from somebody else I have been teaching this for the last ten years I train my patients so that the mother will keep the baby away from the rest of the household if any of them have a cold Many of my patients act on that point of their own volition The school child is a very common source of infection to the young baby School children are continually bringing new germs The first baby in a family often escapes colds because it has *not* this source of infection, but in the same family the following babies may continually have colds because the older brothers and sisters are bringing home infections which are more serious to the younger children I think the term "grip" should be used When we speak of grip nowadays, we mean any acute infectious condition of the respiratory tract

Dr H M McClanahan, Omaha I wish to call your attention to two points First—and I am a little surprised Dr Southworth did not mention it—in a series of eleven cases of nephritis, which I reported last year, in five the only etiologic factor was a common cold I believe we frequently have nephritis as a sequela of common colds The second point is the infection of the baby from a nursing mother with a cold I believe that the child can be prevented from taking the cold from the mother if the mother is careful to wear a mask or handkerchief over her nose and mouth when coughing or sneezing

Dr G D Scott, New York It does not seem to me that the cold alone is to be taken so much into account as the condition of the fertile soil, caused by the 'cold," in which bacteria can be implanted In making a clinical study of many cases of 'colds," in the Boston City Hospital, the New York hospitals and in private practice I have found that a large number of the cases have been diphtheritic These colds cause a fertile soil and the influenza bacillus or the diphtheria bacillus is implanted in the nares and reaches the accessory sinuses, the antrum of Highmore, and causes long continued suppuration or chronicity

Dr LeGrand Kerr Brooklyn We should not forget in the study of the bacteriology of these cases that in healthy children there is often present the diphtheria bacillus, the pneumococcus, and various other bacteria, and yet the child may remain in apparently perfect health If we jump at a conclusion in our laboratory work, we shall often assign as a direct cause for these infections bacilli which have no bearing on them until later That is, they are not the primary cause, but are simply present, as they are present in a large proportion of perfectly healthy normal children But they become active factors later in the development of subsequent complications and sequelae, because, as has been mentioned, a soil has been prepared for their development These cases are not prevalent during the heated term, they are prevalent during the winter months wherever children gather in large numbers The common treatment is to house the child up at the first sign of any coryza I believe that is one of the prolific causes of the complications which follow Whether it is in the winter or in the summer, the child should be protected from complications by receiving plenty of fresh, pure air This is something which will more certainly and more quickly limit the occurrence of complications than any other treatment that we can employ It is the avoidance of complications that we seek Isolation is not enough These children do well in summer because of the compulsory fresh air they must have, but in winter they are usually housed up I have within the last few years insisted on the fresh air treatment of all colds and coryzas It has accomplished more in the elimination of complications than any other method of treatment I do not think the temperature of the fresh air has any particular bearing We know as a physiologic fact that no matter what the temperature of the inspired air as it is taken in through the nostrils, it is circulated through the sinuses and reaches the lung at an equalized temperature, and with a definite amount of moisture It is immaterial whether the inspired air is at 70 or 40, when it reaches the lung it reaches it at a uniform temperature in any child

Dr J P Sedgwick, Minneapolis I think we are all agreed on the importance of what Dr Southworth has brought forward and appreciate the character of his work I know Dr Southworth is not entirely satisfied with the naming of this condition, and yet I believe that the first step in overcoming it is to correct the false name which has been used for so many years, that is "cold" Dr Southworth has partially avoided this by calling the cases infectious colds He speaks of the children being brought down into the drawing room, where they are often exposed to infectious conditions These children are usually "wrapped up so that they will not catch cold" and brought down in fancied security I think that if we could unite on some term whereby we would leave out the term "cold" and bring out the infectious character of the condition, we would bring about better results

---

THE OCCURRENCE AND ETIOLOGY OF CLUB-FOOT *

ALBERT EHRENFRIED, M D
Junior Assistant Surgeon Children's Hospital
BOSTON

I have been interested in running through the cases of congenital talipes entered on the records of the Orthopedic Out-Patient Department of the Children's Hospital during the past five years The records of this period, under the filing system, are comparatively easy to handle, and previous records offer little detailed information My figures have to do chiefly with the occurrence of this deformity

The number of new patients applying for treatment for congenital club-foot during this period was 232, out of a total number of 4,543, or about 5 per cent of the clinic The number has increased steadily, being in 1907, thirty-one, in 1908, forty, in 1909, forty-six, in 1910, fifty, in 1911, sixty-five This includes all types of congenital deformity, and care has been taken to exclude cases of contracture secondary to paralysis or scar-tissue formation, deformity from trauma, and doubtful cases of all sorts The majority of the cases have been under my observation

During the year 1911, 16,931 babies were born in Boston Of these 1,662 died before reaching the age of 6 months, approximately the average age at which infants are brought to the hospital, and may therefore be eliminated Of the sixty-five new cases of congenital club-foot which appeared at the clinic during this year, seventeen were in babies born in the city of Boston If we accept the estimate that of all the cases of club-foot occurring in Boston in which the patients live long enough to be treated, nine-tenths appear eventually at the Children's Hospital, we can conclude that club-foot appears in this community, roughly speaking, once in every 816 births

The incidence of club-foot has been variously estimated at one in 646 (by Chaussier 100 years ago), one in 1,903 (by Lannelongue fifty years ago), and one in 2,000 (by Little thirty-five years ago) Rudaux and de Lorier[1] give statistics for another purpose which show that club-foot appeared eighteen times in approximately 20,200 births at the Beaujon Hospital in eleven years, and nineteen times in approximately 20 900 births at the Clinique Baudelocque in ten years, or once in 1,110 births The proportion of club-foot to the total number of anomalies and monstrosities, according to their figures, was one in ten

---

* Read at a meeting of the Orthopedic Club April 25 1912

[1] Rudaux and de Lorier The Influence of Syphilis on the Production of Anomalies and Fetal Monstrosities Ann de gyn et d Obst, September, 1911, p 400

Of the total of 232 patients 185 exhibited equinovarus, forty-six some other type of deformity, and one had equinovarus of one foot and another type of deformity of the other. That is to say, equinovarus appeared four times as often as all other types of congenital talipes combined, and cases of combination of equinovarus and another type of deformity were rare.

Next in frequency to equinovarus came calcaneovalgus, which appeared in twenty-nine cases, then valgus in five patients, varus in five, equinus in four, calcaneus, calcaneovarus and equinovalgus in one each. I myself have seen but few cases which could not be well classified as either equinovarus or calcaneovalgus. All cases of double deformity in this series showed the same type of talipes in both feet.

I will say in explanation that I have distinguished two types of calcaneovalgus, the fixed, in which the foot is maintained in the position of deformity, and what I have called the potential type, which is far more common, in which the foot hangs flaccid in normal position, but can be made to assume with little or no force the position of extreme deformity. This type is frequently overlooked, or else it is called congenital flat-foot. I have found it to be a frequent cause of delayed walking in children apparently normal.

Why an equinovarus should tend to maintain its position and a calcaneovalgus should be lax is readily explainable. When the fetal foot is forcibly maintained for a considerable time in the equinovarus position the dorsiflexor muscles and the peronei are stretched, while the calf muscles, the plantar flexors and the tibials on the other hand are relaxed, so that they contract and in time become permanently shortened, and the position of the deformity is eventually fixed. With the foot in the calcaneovalgus position the plantar flexors, the calf muscles, and the posterior tibials are stretched. The opposing muscles tend naturally to shorten. But these muscles run to the foot under the annular ligament, making an acute angle, so that they cannot contract. If the deformity is marked, they are stretched, become lax, and the foot hangs flaccid as soon as the causal pressure is removed. There is sometimes sufficient shortening of the peronei, which have a separate annular ligament, to hold the foot in the position of deformity for a few weeks after birth, and this class constitutes the "fixed" type.[2]

One hundred and sixty-one patients were male and seventy-one female, or 69 and 31 per cent, respectively. The proportion of males, however, was somewhat higher in the equinovarus cases (71 per cent) than in the other types of deformity (61 per cent).

There were 130 cases of double club-foot as compared with 102 cases of single deformity, or 56 and 44 per cent, respectively. Of the cases of single deformity 59 per cent were right sided and 41 per cent were on the left. The proportion of double club-foot was somewhat lower (55 per cent) in the equinovarus cases than it was in the other types of talipes (61 per cent).

Some evidence as to heredity or family influence was gained from the records of fourteen cases, all cases of equinovarus. In other words, fourteen patients with equinovarus were related to persons who had some congenital defect. In eleven of these cases the family deformity was club-foot, and this occurred once in the father of the patient, once in the mother's cousin, twice in an uncle, five times in brother or sister, and twice in two brothers or sisters. Eight of these fourteen patients were male and six female, and the deformity was double in twelve.

I attempted to arrive at an estimate of the nationality of the parents. The records give no help in children born in this country except the name of the parents. On this basis and from personal acquaintance I have concluded that 34 per cent of the parents are of Anglo-Saxon, Scotch or native American stock, 31 per cent of Irish birth, 9 per cent of Russian Jewish birth, 9 per cent of Italian, 6 per cent of Scandinavian, 4 per cent of French Canadian and 7 per cent of Polish, Greek, Syrian and other extraction. All the races which we ordinarily see at the Children's Hospital were represented except the colored, of which there was no example in this series, although colored children are frequent at the clinic. I was struck also by the small proportion of Germans, of whom there were only about 1 per cent.

There has been some discussion as to the frequency of the occurrence of club-foot in twins. There is a theory several centuries old that the deformity is more common in multiple pregnancies than in single, for the reason that there is less room in the uterus and the fetuses are crowded together. This has recently been denied by Rugh[7] who, basing his conclusions on the literature and on a study of records of maternity hospitals, declares that in twins the deformity is unusual.

In this series eight patients were recorded as being one of twins and one was of triplets, making nine examples of multiple pregnancies in all, or 4 per cent. This is about four times the normal rate of occurrence of multiple pregnancies. The cases of multiple pregnancy were only half as common (3 per cent) in equinovarus patients as in those with other deformities (6 per cent). Five of the patients were male and four female, and the deformity was double in six cases. No patient showed any other deformity. Of twins two were brothers; in five the other twin was normal and in one the other twin died at birth. Of the triplets one was normal and the other one had died.

Some interest attaches to the size of the family in which club-foot occurs. Mothers who bring their infants to the hospital are asked how many children they have had. There is only an occasional exception to the rule that club-foot patients are brought before they are 9 months old, so we may take it for granted that the number given by the mother represents children borne before the patient. My figures on this point will err, therefore, in making the number previously borne slightly too large. Sixty-eight, or 30 per cent, of the patients were first born. In the other 70 per cent the average number of children previously borne was 3[illegible]. The number ran up as high, however, as eleven and twelve, and there were six instances of previous families of ten or more.

As regards labor, the 200 histories which record it give thirty-three, or 16 per cent, as being difficult, necessitating the employment of ether and forceps. Of the deliveries 78 per cent were stated as being normal. Two cases were given as breech presentation and nine infants were premature. The percentage of premature births was less in equinovarus ([illegible] per cent) than in other types of deformity (15 per cent). Several full-term babies were so puny and undersized as to resemble premature infants.

[7] Rugh [illegible] Orthop Surg [illegible]

The occurrence of other congenital deformities in conjunction with the talipes was by no means uncommon Other congenital deformities were present in thirty-one cases, or 13 4 per cent They were only half as frequent in equinovarus patients (11 3 per cent) as in other types of club-foot (22 per cent) Double club-hands were present in six cases, contracted knees in six, mental deficiency in four, spina bifida in three, dislocated hip in three, dislocated knee in three, hydrocephalus in two, and two were blue babies, amniotic groove, congenital scoliosis and cleft palate occurred once each Other developmental deformities or deficiencies of the limbs occurred in eleven patients Umbilical and inguinal hernia were observed several times, as was also a condition of the foot in which the heads of the metatarsals are arranged in a semicircle, so that the first and fifth nearly approximate, and which I have called "prehensile foot" In eight of the babies there were multiple deformities

It is interesting to compare these findings with the statistics of Rudaux and de Lorier, which, being compiled for other purposes, must be considered unbiased Of the thirty-seven cases recorded, twenty-three, or 62 per cent, were uncomplicated and fourteen, or 38 per cent, were complicated by other congenital deformities Nine (or 24 per cent of the total) exhibited spina bifida, two spina bifida and hydrocephalus, one cleft palate and hypospadias, one club-hands, and one amniotic groove and digital malformations In explanation of the discrepancy between their figures and mine it may be stated that in cases which are badly complicated the patients are likely to die without coming to treatment for the deformity, moreover, there were possibly cases of mild grades of club-foot in their series which were overlooked, the observers not being orthopedists

A consideration of these accompanying deformities, in a way offering confirmatory evidence as to the forces involved, leads to interesting speculation on the etiology of the condition. In four of the above-mentioned cases occurred excellent examples of the so-called perineal position of the feet The young infant in relaxation would bring the knees up on the abdomen and flatten the feet against the perineum in the position of deformity, just as if he were trying to make himself up into the smallest package possible There is no question in my mind but that this represents the effect of an intra-uterine condition, and is the mechanical result of close packing of the fetus in the later months of pregnancy Other definite evidences of a similar nature occurred in the bowing of the shaft of one or more bones of the leg, which was observed four times in this series, marking a point where the crossed legs fit into each other, and of such a sort as to allow a closer approximation of the limbs to the body

All sorts of more or less tangible theories as to the etiology of club-foot have been offered, and the literature on the subject is considerable No explanation that I have met seems to cover the entire field satisfactorily The theory which I have adopted is simple and for the present, I think, adequate

Congenital club-foot is the result either of some tendency to the production of the deformity inherent in the fertilized ovum, or of causes acting after the implantation of the ovum If it preexists in the germ, we may call it germinal or inherited It seems fairly clear that heredity is the determining factor in a certain small percentage of all the cases of talipes, just as it is in such deformities as polydactylism, polymastia, etc There are well-authenticated cases of club-foot appearing in several members of a family, and cases in which father apparently transmits it to son Little has traced it on the paternal side through four generations Adams cites a case of a man of 46 having double congenital equinovarus, with five club-footed children, a club-footed nephew, and a club-footed grandchild Lannelongue tells of a woman of 25 with double congenital equinovarus, whose father and whose baby have the same deformity In my series, 5 per cent gave a history of the occurrence of club-foot in a near relative, and this figure, corresponding exactly with that of Ketch,[4] who found ten in 196 cases showing unmistakable heredity, may be taken to represent the approximate frequency of inherited club-foot It is significant to note that these were all cases of equinovarus, usually double, and in no case accompanied by any other deformity

The causes which act on the organism *in utero* may be divided into two distinct classes early causes, acting on the ovum or young embryo, and late causes, which exert an influence on the developed fetus The deleterious agencies which may work on the ovum have been expounded by Professor Mall in his work on "The Causes Underlying the Origin of Human Monsters" He demonstrates that what he calls a faulty implantation of the ovum, as in the presence of endometritis and other diseased conditions of the uterus, and in tubal pregnancy, may lead through interference with the nutrition of the embryo to degenerative changes of such nature that the embryo dies, or, if it survives to term, develops into a monstrosity In certain of the minor grades of monstrosities, as spina bifida, hydrocephalus and cleft palate, the fetuses are viable, and in such cases of slight malformation, accompanying the general retardation of development, there is likely to be marked impairment in the development of the extremities In all cases of this class there is a tendency to an increase in the quantity of amniotic fluid

The only definite basis on which we are justified in classifying cases of talipes as being of embryonic origin is the association with other conditions which we are reasonably sure are the results of arrested or impaired development *in utero* As such we may class spina bifida, hydrocephalus, certain developmental deformities or deficiencies of the limbs, cleft palate, constriction rings and patent foramen ovale, and I am inclined to place in this division cases of premature birth and of mental deficiency, making a total of 10 per cent I do not believe that, as Mall would allow one to infer, an embryo can be subjected to a general nutritional disturbance early in its history, even if only temporary, develop normally and be delivered as a healthy well-developed child with nothing to show for it but a club-foot

Finally comes the third class of cases, to which the majority evidently belong, arising from mechanical causes acting later in the development of the fetus The theory of the mechanical origin of club-foot, and, by the same token, of club-hands, contracted or recurved knees and dislocated hips, which frequently complicate club-foot, has appealed strongly to most men who have concentrated their attention on the study of this deformity Hippocrates and Ambroise Paré expressed themselves definitely in its favor, and the theory has been advocated in one form or another by a long line of more modern students, including Cruveilhier, von Walter, Bellartin, Ferdinand Martin, Duval, Volkmann, Kocher, Bruckner, Holmes Coote, Boyer and Parker

---

[4] Ketch Etiology of Club Foot Tr Am Orthop Assn, 1892 v 159

Just how the deformity is produced cannot always be definitely stated. The cases that occur in twins or in the presence of oligamnios or of uterine tumors can be explained by a crowding of the fetus. In some cases we often find evidence of mechanical interference with intra-uterine development in the infant itself. Frequently, as already stated, a young infant with club-foot, if stripped and allowed to relax, will voluntarily reconstruct the position which it maintained in the latter part of pregnancy; it will bundle itself into a cast of the interior of the uterus, so that the action of the uterine wall in causing or maintaining the deformity is strikingly evident. There are certain type positions which the feet assume. Many cases of this sort have been pictured by Martin, Parker, Turner and Whitman. Other evidences of uterine pressure in such cases may be seen in the grooving of crossed limbs, in the imprint of a foot on distorted features, and in the occurrence of hydrocele or inguinal hernia as the result of local pressure.

A decrease in the quantity of amniotic fluid need not necessarily be postulated; the foot may be caught in some position from which it cannot extricate itself, as in the axilla or over the shoulder, or the two feet may interlock in such a way as to interfere with normal development, which conditions have been observed, or the fetus may occupy a disadvantageous or constricted position from which it is unable to free itself by its own activities, so that the foot is maintained for a considerable time in one position, and the position of inversion which is normal in early fetal months is not allowed to correct itself, in accordance with the natural course of events. Too little is known, even by obstetricians, of the position which a fetus may assume at different stages of pregnancy, of the factors which interfere with the natural changes in position, and how far such modifications of the normal may exert a deleterious effect on the development of the fetus. There is, however, a great deal of promise in the systematic study of the pregnant uterus by the *x*-ray, which recent developments and refinements now make possible.

In a considerable proportion of cases it is probable that external and accidental influences play an important rôle, and in some instances the records have given a hint as to a mechanical causal factor, real or imagined. For example, the mother has occasionally referred to a trauma or shock which she suffered while carrying the child. One said, for instance that the baby was "crushed in the womb." The occurrence of tumors of the pelvis or of other pelvic disease in the mother was never definitely ascertained. Occasionally I have been told that miscarriage was feared at some time during pregnancy, and a few times I elicited the information that excessive coitus was indulged in during pregnancy.

The one constant factor which I have arrived at is the rather poor social status of the patients. Practically without exception the mothers were of a class that is compelled to do a certain amount of work during pregnancy. I have found that some were employed in factories or elsewhere, and some were in service as domestics; a few were the support of their families. The majority of the mothers were housewives doing their work without help, and sometimes for families of considerable size. A certain number have stated with some pride that they did their own work up to within a few hours of delivery. Others have worked hard at the sewing-machine.

The statement has been made that club-foot and other congenital deformities appear frequently in the children of those who have reasons for hiding the pregnancy, as the unmarried and those in service. This series offers no further corroborative evidence of this than the fact that in three cases illegitimacy is stated. Personal observation leads me to think that in certain other cases the child was not accorded a very grateful reception.

The easy criticism of these findings may be offered that they depend on statistics taken from an institution in which one would naturally expect to deal with the poorer class of people. But the average financial condition of the families of which the children are being treated in the orthopedic out-patient clinic at the Children's Hospital is much better than might be expected. Many are in good circumstances, coming from other cities and states and willingly put themselves to a considerable expense to carry out a long course of treatment. And on the other hand, club-foot is not frequently seen in the private practice of orthopedic specialists of this community, among the wealthy. I have seen a few such cases, but in each instance there have been accompanying conditions which suggest an embryonal rather than a mechanical etiology.

SUMMARY

Congenital talipes occurs approximately once in every thousand births, and in one-tenth of all infants with congenital deformities. In the past five years at the Children's Hospital orthopedic out-patient department 232 new cases have been treated, constituting 5 per cent. of the new patients for that period.

Of the two important types equinovarus constitutes about 80 per cent. and calcaneovarus 20 per cent. Forms which cannot be classified under one or the other of these divisions are rare. The fixed type of calcaneovalgus is less common than the potential type. Equinovarus on one foot and calcaneovalgus on the other is quite unusual.

About 70 per cent. of the patients are male and 30 per cent. female; 55 per cent. are double and 45 per cent. single. Of the single cases 60 per cent. are right and 40 per cent. left.

Club-foot is known to have appeared in near relatives in 5 per cent.

About 33 per cent. of all the patients are first-born; in about 16 per cent. delivery is difficult; in 4 per cent. birth is premature and in 2 per cent. illegitimate. The condition appears in twins or triplets four times as often as in single pregnancies. It is accompanied by other congenital deformities in 12 per cent. of all cases.

There are three etiologic factors to be considered: heredity, evident in 5 per cent.; early intra-uterine causes depending on faulty nutrition from a diseased condition of the chorionic villi, evident in 10 per cent., and mechanical causes operating later in intra-uterine life, accounting probably for most of the remainder. In the last class poor hygiene of pregnancy and work during pregnancy are undoubtedly causal factors of considerable importance.

THE VALUE OF THE SOCIAL SERVICE DEPARTMENT TO THE CHILDREN'S DISPENSARY *

MAURICE OSTHEIMER, M.D.

Associate in Diseases of Children, University of Pennsylvania; Assistant Visiting Physician to the Children's Ward and Physician in Charge of the Children's Dispensary, University Hospital

PHILADELPHIA

So varied are the ways and means by which the social service department may be of assistance to the dispensary physician that the title of this paper might just as well have read "The Values of the Social Service Department to the Children's Dispensary." Advice and directions, although carefully explained to the person who accompanies the young patient to the dispensary, are frequently received with scant attention and sometimes partially or even totally forgotten by the time the child has reached home. Even detailed directions, minutely written out, may never come into the hands of the child's parents. And finally, even if the note does reach the parents, the physician's advice and directions may nevertheless remain unheeded.

It was primarily with the object of having our directions correctly carried out that the social service department two years ago began to work with the children's dispensary. It was soon found, however, what a wide field of usefulness was opened to the visiting nurse and through her not only to the physicians at work in the dispensary but also to the philanthropic men and women supplying the funds to carry on the work.

WORK OF THE NURSE

When a sick child is observed in the dispensary, explicit directions are given to the trained nurse the same afternoon, sometimes while the child is present, sometimes later. If the nurse is in the room when advice is given, the child will recognize her when she visits the home, as she does within twenty-four hours. The same written orders which have been explained to the child's mother are also given to the nurse. On her arrival at the child's home, she explains the physician's directions fully and with great detail and shows the mother how to carry out each separate order. She sees that the sick child is correctly cared for, instructs the mother in preparing the food properly and in giving water to drink at regular intervals, in the matter of bathing or sponging, in correct bedding, covering and clothing, in nursing, cleanliness, hygiene and sanitation. She shows which windows and doors should remain open, when to leave the child alone for sleep, how to dispose of the excreta, how to keep other persons out of the sick-room — in short, how to make the conditions as nearly ideal as is possible under existing circumstances. If she finds the surroundings absolutely impossible, she reports the conditions to the physician, or in urgent cases makes arrangements for the child's immediate removal to the hospital.

She also learns the financial conditions of the entire family, the sanitary conditions of the whole house, the number of families living in the house, the cleanliness of furniture and bedding, the presence of unnoticed or untreated illness, defects or deformities among other members of the family or in a tenement house of the neighbors' families, whether work is done on the premises and, if done, what kind of work, and what sort of work is performed by the various members of the family. She tries to refer these people to the different departments of the hospital for whatever treatment she thinks necessary, as, for example, to the nose and throat dispensary for adenoids, to the nervous dispensary for electricity and massage, or to the laboratory for tuberculin or Wassermann tests, she sees that children return to the children's dispensary from time to time, sends other children for examination or treatment, secures hospital care for those too ill to visit the dispensary, sends some to the seashore, to special sanatoriums or to open-air schools, gets out-door jobs for convalescents and other employment for others, gives careful instructions to those about to become mothers, and refers the needy and undecided to the chief of our social service department, Miss Helen Glenn, for her counsel. It is a pleasure for me to acknowledge here our great indebtedness to Miss Glenn and her assistants.

In cases in which there is possibility of an acute infectious disease, and in any case of gonorrhea, syphilis or tuberculosis, the nurse arranges for the isolation of the patient and instructs adult members of the family as to the means and manner of preventing further contagion in that household. If isolation is impossible, she persuades the family to allow the child to be removed to the special hospital for the treatment of contagious diseases. In case of extreme poverty, or when there is insufficient food or clothing, she tries to find means to ameliorate existing conditions. The patient is usually taken to the hospital, and some charitable organization is asked to investigate and relieve the family. When the nurse suspects that children may have been or are being abused, she directs the attention of the Society to Protect Children from Cruelty to the family. She may also arrange for the free dispensation of medicine to members of such families, on the physician's request.

The nurse may also be instructed to leave printed "diet" and "don't" lists in homes in which there are children, to wash out a stomach or to irrigate the intestines, to give special baths, spongings, oil rubs or massage, and to give minute instructions for the preparation and administration of food and medicine. She may also be able to secure specimens of sputum, urine and feces for examination, if the physician desires. She tries to impress on pregnant women the importance of care before and after delivery, and urges mothers to keep their infants with them; she also tries to correct certain bad family habits, such as the lack of toothbrushes, the common custom of leaving food uncovered, exposed to dust and flies, a family, including one or more sick children, congregating about the kitchen range in cold weather with doors and windows all tightly shut, or the prevalent habit of children rushing off to school without having had any breakfast or after hastily swallowing some fresh cinnamon bun or roll, with a drink of tea or coffee.

Should there be no older person to accompany the child to the dispensary, the social worker tries to find some one to bring the patient to the doctor regularly. If a child should suddenly grow worse, she arranges to rush both mother and baby to the hospital, and if the person who accompanies a child should chance to become ill or to faint while in the hospital, some one is provided to see that they both reach home safely. The remarks of the visiting nurse have been the means of stopping, in many homes, not only the use of patent medicines but also the old custom of "baby pacifiers." Many children with defects of speech, spinal curvature, back-

* Read in the Section on Diseases of Children of the American Medical Association at the Sixty-Third Annual Session, held at Atlantic City, June, 1912.

wardness, adenoids, otitis or enuresis, which so many parents consider incurable, have been brought for treatment and improved if not cured. Besides, places as domestics have been found for mothers with or without their children. It would not be difficult to refer to many instances of what appeared to be trifling matters in which the existing problem was solved with the aid of the social service department, eventually making an entire family again independent.

In the feeding of infants and children much has been accomplished. The nurse, who continues her visits even after the child seems well, can encourage breast-feeding until warm weather is over, can keep away all other foods, can teach the habit of feeding at regular intervals, can arrange for a wet-nurse if the physician wishes, or can teach the proper preparation of the baby's food under the doctor's orders. She can oversee weaning when the time arrives, and the general care and feeding of the older children, preventing the common indulgence in sweets, fresh cake and bread, especially between meals, and the overindulgence in tea, coffee and fried foods of all kinds.

Our best results were achieved in the acute gastro-intestinal attacks of infants in the summer. Here the elimination of the cause, which is always the food, saves the baby. No matter how carefully, how urgently or how decidedly the physician tries to impress on the baby's mother the importance of this fact, a friend, a neighbor or frequently the baby's grandmother persists in feeding the baby. But when a nurse comes into the household daily, prepares the boiled water or lactose solution and makes the mother understand, often through an interpreter, that any food may kill her baby, we get results. Three of our case histories follow, one from each of the summer months.

REPORT OF CASES

CASE 1.—Baby C, 18 months old, of Italian parentage, the only child (one of twins, the other having died nine months before) was brought to the dispensary, June 28, with a history of vomiting and diarrhea for three days. She had been partaking of all the food that her parents ate. Her temperature was 103.2 F. All food was stopped and only lime water and cinnamon water and 5 per cent. lactose solution were allowed, beginning with one-half ounce at a time need. The nurse, who was present in the dispensary, visited the family the same afternoon and showed the mother how to prepare the solution. The next day, as vomiting had ceased, the quantity of lactose solution was gradually increased; the day after that whole milk was added and this was readily increased until the mixture was one-half milk. Five days after the nurse's first visit the baby was well, on undiluted milk. The mother has been very grateful, bringing the child back for every trifling ailment.

CASE 2.—Baby A, 6 months old, ninth child of Italian parents, was brought to the dispensary July 14. He had been weaned almost two months earlier and was taking 5 ounces of mixture of milk and water (2½ ounces of each) every three hours. He had been vomiting and his bowels had been loose and stools green for three days, though he had refused his bottle; his mother kept urging food on him. His temperature was 104.4 F. As the mother refused to allow him to remain even for a day in the hospital he was given castor oil and sent home. The nurse visited him that same afternoon, showed the mother how to sponge him and to prepare the lactose solution. Two days later he was put to both breasts every three hours for five minutes, followed by the lactose solution. This was continued, a little milk being added to the lactose solution. In six days he was back on the breast solely and was doing well. In this family some of the other children were brought to the hospital for treatment and diagnosis and others were sent to the seashore.

CASE 3.—Baby D, the fifth child of Russian parents, with a tuberculous mother and sister, was brought to the dispensary first in July with indigestion because of being nursed too often and being allowed to take too much at each nursing. When 3 months of age, in August, he was brought back ill with diarrhea and vomiting and a temperature of 101.4 F. On being taken from the breast, given a dose of castor oil and put on lactose solution he fully recovered in twenty-four hours. In this family no single member has been without some benefit from the work of our social service department.

During the summer of last year, for the first time in ten years, I did not have to sign one death certificate in the dispensary and so far as I can discover only two of our patients were admitted to any hospital in a moribund condition. We were unable to observe a single case of cholera infantum and the only really ill infants were found among the foreigners, the Russians and Italians. From this it is evident that while our former campaigns in the education of mothers in preventive medicine have benefited those who could talk and understand English, we have not yet been able to reach the foreign population. While the nurse did good work in preparing the feedings, she also explained to those women the ordinary rules of hygiene both before and after delivery, fresh air, bathing, water to drink, clothing, covering and the myriad trifling details of which so many mothers are woefully ignorant. Her other great work was in urging mothers *not* to part with their children!

It is then no idle boast for me to terminate with the statement that with the assistance of our social service department the children's dispensary has been able to save many lives (especially among infants of foreign parentage), much contagion, illness, worry and even expense. It is my hope that the possibility of usefulness in this field may deeply impress you. Far as our work has gone, the field of usefulness to humanity seems still wider. There can be no doubt that contributions will never fail to be forthcoming to support work of such a philanthropic character.

2202 De Lancey Street.

ABSTRACT OF DISCUSSION

DR. H. J. GRAMLING, Milwaukee: There is one thing which I think would help in this work. It should be made harder for the people who feed their babies sausage to get death certificates. They should be made to understand that a meal of sausage for babies is as dangerous as a dose of arsenic. In Milwaukee every birth is reported in the papers. Within the next two or three days the mother receives through the mail literature on soothing syrup and babies' food. At that rate the state is really helping the patent medicine people to introduce poison into the household. I do not know whether this is simply a local condition peculiar to our town or not. If it is a general condition I think this Section should take action to bring it before the postal authorities.

DR. M. H. FUSSELL, Philadelphia: At the University of Pennsylvania we owe the installation of the social service department to the late Dr. John Musser. Five years ago he visited Boston and was impressed with the social service work in the Massachusetts General Hospital. He then by personal solicitation and contributions raised a large sum that started the social service department. The effect of the social service work has been marvelous. Perhaps the most brilliant results have been in the Children's Dispensary. For instance, in the care of tuberculous [illegible] been most helpful When we get a case of tuberculosis, we at once follow it up by one of the special social workers, under the superintendent, who makes it her duty to visit the home and see that the instructions of the physician are carried out, to look after the general hygiene of the family, to report other cases, etc Dr Ostheimer's paper may have conveyed the idea that the nurse or the social worker who followed the case directed the child to be taken to the dispensary, and have the tonsils and adenoids removed, or to be taken to some other place for medical attention That is not the fact One of the things that is impressed by the head of the social service department on her subordinates is that the directions of the physician in charge of the patient be carried out, if anything additional has to be done, that particular physician is consulted The difference between our treatment now and previous to the last five years is marvelous We know exactly how our patients are doing, whether well or ill Every dispensary in the University of Pennsylvania, if it so desires, can refer a case to the social service department, and that case is followed up If the patients do not deserve free medical service, they are directed to the proper physician Thus we overcome the abuse of free dispensaries

Dr T B Cooley, Detroit Anyone who has done work among children of the poor knows that we are not doing more than a fraction of what we should do when we simply see them at a dispensary and prescribe for them, for we are not at all sure that our directions will be carried out or administered properly The practice of medicine among the poor, and especially among children, is becoming more and more to be quite as much sociologic as medical, and this must be taken into consideration We should all realize that the time has come when we are not doing justice to our patients unless we go into sociologic as well as medical problems

Dr D J M Miller, Atlantic City, N J Dr Gramling spoke of the "patent medicine" people distributing samples of soothing syrups In Atlantic City—a city of about 48,000 permanent inhabitants and many more temporary ones—two of the largest proprietary food manufacturers in the country maintain two nurses who will go to any house and instruct the mother and will take full charge of the baby, furnishing all material free Last fall I saw a child with scurvy fed on malted milk by one of these nurses Physicians send for these nurses to feed the babies—quite a commentary on the pediatric teaching in some schools This, I believe, also occurs in other cities, Philadelphia for instance Social service, I think, will combat this and many similar evils

Dr Charles Douglas, Detroit Dr Miller's remarks reflect on the medical teachers as being neglectful We might as well draw the line sharply and clearly It is not the fault of the pediatric teachers they are not doing their work poorly It is carelessness or laziness of the students who go out into practice and just slide along the road on which they have the least trouble We have to contend with the inherited idea that the old woman knows better how to feed the baby than the physician does It is the graduate who passes out and who ceases to be guided by the instructions which he has received from his teachers who errs We have also to contend with the historical thoughts handed down to students by men who studied medicine twenty five or thirty years ago Let every one of us who is connected with a medical college read up the pediatric thoughts and utterances made by other members of the faculty with which he is associated and let him see how many of those men are putting out the right ideas in pediatrics We are in a state of evolution It behooves us all to work along that line remembering that in the gradual process of evolution the teaching faculties will gradually come up to that point in pediatric thought where we are trying to place our students at present No doubt our young students who are being taught to day and who will teach pediatrics later will be better examples than many of the teachers of to da , who were not taught correctly It is just as impossible for me to give instruction in recent surgery, of which I know little, as it would be for these men to give instruction on pediatric subjects of which they know very little

Dr M Ostheimer, Philadelphia I hope I did not give the impression that the nurse does all these things on her own responsibility She always refers the children to me Adults are referred to the various other dispensaries, and if they do not belong there, the chief refers them to someone else

---

THE INJECTION OF RHESUS MONKEYS WITH BLOOD FROM PATIENTS WITH "RHEUMATIC FEVER"*

OSCAR M SCHLOSS, M D
NEW YORK

The clinical picture of acute rheumatic fever suggests strongly that the disease is due to some infectious agent Although several microorganisms have been isolated from cases of this disease yet none has been obtained with sufficient frequency to establish conclusively a direct etiologic relationship For this reason it seemed of interest to attempt to determine whether the disease might be due to some undiscovered virus which could not be isolated by the usual methods

Defibrinated blood obtained from patients with rheumatic fever was injected into rhesus monkeys Only typical cases were selected The blood was taken before active treatment was begun and during the acute stage when the disease was spreading from joint to joint—the time when it seemed most probable that the causative agent would be present in the circulating blood The blood was obtained in large test-tubes, defibrinated by means of glass beads and injected within three hours from the time it was obtained Every effort was made to keep the blood warm

PROTOCOLS

Monkey 1 —Five c.c of defibrinated blood were given intraperitoneally No symptoms developed One month later an intravenous injection of 15 c.c of defibrinated blood from another patient was given The animal remained entirely well

Monkey 2 —On the first injection this animal was given about 3 c c of defibrinated blood intravenously and about 2 c c subcutaneously He was watched for one month, no symptoms occurred A second injection of the same amounts of blood from another patient was given The result was negative After an interval of three weeks a third injection of 10 c c. of defibrinated blood was given intravenously The animal remained well

Monkey 3 —Ten c c of defibrinated blood were injected intravenously The result was negative

Monkey 4 —Twelve c c of defibrinated blood was given by intravenous injection No symptoms occurred [1]

These experiments fail to show that the blood of rheumatic fever patients contains an infectious virus capable of affecting rhesus monkeys Either the causative agent of the disease is not present in the circulating blood in sufficient quantity, or, if it is present, rhesus monkeys are immune to its influence

The material used in the experiments was obtained from the medical services of the New York and St Luke's hospitals

172 West Seventy Ninth Street.

---

* From the Pathological Laboratory of St Luke's Hospital, New York The expense of this research was defrayed by the Bush Fund for the Study of Arthritis

[1] Defibrinated blood from three of the patients was injected *into the ear veins of rabbits in the following amounts* Rabbit 1 was given 2 c c Rabbit 2 3 c c and Rabbit 3, 4 c c Two guinea pigs and three rats were given intraperitoneal injection of 2 to 4 c c of defibrinated blood from the same patients With the exception of the direct effects of the injection of the foreign blood none of the animals showed any definite symptoms.

THE VALUE OF SERIAL RADIOGRAPHY IN GASTRO-INTESTINAL DIAGNOSIS *

LEWIS GREGORY COLE, M.D.
NEW YORK

This is essentially a summary of a series of three articles on the "Radiographic Diagnosis of Gastro-duodenal Lesions," the first two published respectively in the December 1911 and the March, 1912, issues of the *Archives of Roentgen Ray*. The third will appear in an early issue of the same periodical.

Two or three radiographs are sufficient to determine the size, shape and position of the stomach. For the convenience of indexing the different types may be grouped into four classes: (1) cow horn, (2) text-book, (3) drain trap, (4) fish-hook (Figs. 1, 2, 3, 4), but in cases of suspected pathologic conditions one is not justified in making a diagnosis unless serial radiography is employed. This term is applied to a series of from fourteen to twenty-four radiographs of various phases of different cycles, which, when assembled, may be studied individually and collectively, or reduced to a cinematographic size and projected on the screen, giving a graphic and fairly accurate representation of the gastric motor phenomena. The technic of this examination enables the operator to observe on a fluoroscopic screen grossly what is registered in detail on the plate.

This method of examination illustrated in Figure 5, has demonstrated that the motor phenomena of the stomach are complex instead of simple. They constitute a cycle similar to the heart action composed of a systole (Phases 1 to 6), and a diastole (Phases 7 to 10), and the progression toward the pylorus of a series of peristaltic contractions. A cycle occurs about once in three seconds, and at the end of a cycle, a peristaltic contraction should have moved up to the position occupied by the preceding contraction at the end of the previous cycle. If a contraction progresses from its origin to its termination at the pylorus in a single cycle (Fig. 1), that stomach exhibits the one-cycle type of gastric peristalsis. If two cycles are required for it to progress from its origin to its termination, the peristalsis is of the two-cycle type (Fig. 2). If three or four cycles are required, it is of the three-cycle (Fig. 3) or four-cycle type (Fig. 4). The last two are the most common types. The gastric cycle is governed somewhat by respiration, perhaps through the vagus, which supplies impulse both to the diaphragm and to the stomach. This suggests a method by which gastric peristalsis may be stimulated.

That portion of the gastro-intestinal tract previously known as the first portion of the duodenum has the embryologic, physiologic and surgical characteristics of the stomach, rather than of the small intestine. The important part that its radiologic appearance plays in the diagnosis of gastric, duodenal and gall-bladder lesions justifies its being dignified by a name, and the manner in which it sits up on the pylorus so closely resembles a cap that this name immediately presented itself. Radiologically this cap appears to be a continuation of the stomach, and resembles the pars pylorica in size and shape (Figs. 9 to 14). It should be symmetrical, although its shape varies with the gastric cycle and the posture of the patient. The cap surmounts the pylorus, being separated from it by a space of about three sixteenths of an inch, which indicates the normal pyloric sphincter. The gastric and duodenal surfaces of the sphincter should be clear-cut and smooth, and its lumen about one eighth inch in diameter, and centrally located. In cases of adhesions in this quadrant of the abdomen from gastric or duodenal ulcers, or from gall-bladder infection, with or without calculi, the cap is usually the first to suffer limitation in its normal dilatation.

To determine the lumen of the second and third portions of the duodenum *artificial dilatation of the duodenum* may be accomplished by passing a pyloric dilator (Einhorn) into the jejunum. This, when inflated, acts as a temporary obstruction. The bismuth and buttermilk then passes through the sphincter, dilating the second and third portions of the duodenum (Fig. 26).

The gastric and duodenal lesions that may be recognized by the use of serial radiography are:

1. Carcinoma (Figs. 6, 15, 16).
2. Hour-glass contraction (Fig. 7).
3. Adhesions from gastric or duodenal ulcers (Figs. 17 and 18 respectively), or gall-bladder infection, with calculi (Fig. 14) or without calculi (Fig. 20).
4. Dilatation of the pars pylorica from obstruction (Fig. 23).
5. Atonic dilatation (Fig. 24) with or without prolapse of the pylorus.
6. Atrophic contraction (Fig. 25).

The following radiographic findings are characteristic of carcinoma. The lumen of the stomach is encroached on by a nodular growth in the wall of the viscus, with islands or projections into the normal tissue, giving the appearance of finger-prints (Figs. 6 and 16). The growth may progress in the form of a cone (Figs. 6 and 15), terminating at its apex in a small constricted lumen, which may be filled with bismuth or entirely obliterated or the line of invasion may have a worm-eaten appearance with overhanging edges. The area of constriction is constant in size, shape and position, and devoid of peristaltic contractions or rugæ, although it may be filled and emptied during each cycle by the peristalsis of the normal portion.

The characteristics of hour-glass constriction of the stomach are illustrated in Figure 7. The constriction is narrow, having the appearance of a ring with clear-cut edges. It resembles a peristaltic contraction, except that it does not relax during diastole. The upper segment is large in proportion to the lower one, which corresponds in size and shape to a normal empty stomach. A deep crease or spasmodic contraction in the greater curvature near the spleen so closely resembles an hour-glass constriction that at least two series of radiograms must be made with the patient in various postures before one is justified in making a diagnosis of hour-glass stomach.

Adhesions involving the pylorus and duodenum indicate, in a large percentage of cases, the presence of an ulcer of the stomach or duodenum, or gall-bladder infection, with or without calculi. The radiographic indications of adhesions are illustrated in Figures 8, 17, 18, 19, 20, 21 and 22.

1. The lumen of the affected area varies in diameter but does not dilate to its normal size.
2. The rugæ in the affected area show with unusual distinctness, having a crinkled appearance, and usually run obliquely or transversely.
3. The peristaltic contractions are clear-cut in the normal portion, but cease or are distorted when they reach the adhesions.

---

* Read in the Section on Practice of Medicine of the American Medical Association at the Sixty-Third Annual Session, held at Atlantic City, June, 1912.

* Because of lack of space Figures 21 to 26 have been omitted in THE JOURNAL. They appear in the Transactions of the Section and in the author's reprints.

4 The cap is constricted, asymmetrical, displaced or absent
5 The sphincter is not clear cut and well defined, and is much wider than it should be, either on one surface, forming a wedge shaped area, or on both surfaces, giving an annular appearance
6 The second and third portions of the duodenum are angular or contracted
7 The stomach may be bound to an adjacent viscus, and conform in shape to the lines of the liver, gall bladder or colon At the point of adhesions on the lesser curvature peristalsis ceases, and the contraction on the greater curvature becomes deeper, compensating for its absence on the lesser curvature

A small localized constriction in the body of the stomach or pars pylorica, having the appearance of an embryonic hour-glass contraction, associated with a distortion of the rugæ, suggests an ulcer of the stomach, old or new

If the cap is contracted and worm-eaten, but not drawn to the right, and the duodenal surface of the sphincter is irregular, duodenal ulcer should be considered

Extensive adhesions, involving the right side of the pars pylorica, drawing that portion of the stomach to the right and straightening out the greater curvature, the cap being of normal dimensions, but angulated, and the sphincter being normal, suggest gall-bladder infection, with or without calculi

The differential diagnosis of carcinoma from adhesions or hour-glass stomach is very important In extensive cases this may be made with great accuracy, and many non-operable cases may thus be saved the shock of an unnecessary exploratory operation Even in early cases the radiologist can differentiate between malignant and non-malignant lesions with about the same degree of certainty as can the surgeon at an exploratory operation, without a microscopic examination of the specimen It is more conservative, however, for the radiologist to state the character, location and extent of the adhesions, and leave the surgeon to determine the cause The important question is, Do the radiographic findings indicate surgical procedure? If there is any radiologic evidence of malignancy, surgical interference is indicated, regardless of whether or not the symptoms are severe enough to justify this procedure But if there is no evidence of malignancy, the cases group themselves radiologically into three classes

1 Adhesions with or without dilatation of the stomach, accompanied by symptoms sufficiently severe to indicate surgical procedure (Fig 22)
2 A definite lesion without sufficient symptoms to justify surgical procedure (Fig 21)
3 Definite radiographic findings, with obscure but prolonged symptoms, referable to the right hypochondrium

Dilatation of the stomach may be recognized by other methods of examination, but it is of two types, one from pyloric obstruction, and the other from atony Pyloric obstruction, calling for surgical procedure, causes a dilatation of the pars pylorica, giving the prognathian or "under-shot" appearance of a bull-dog's jaw (Fig 23) The atonic type of dilated stomach (Fig 24) is enlarged uniformly, with or without a prolapse of the pylorus But the lumen of the sphincter is not sufficiently contracted to prevent complete evacuation In such cases surgical procedure is not indicated

The atrophic contracted stomach (Fig 25) is high and the greater curvature nearly straight, the cap is absent or displaced, and the peristaltic contractions are wide, showing a lack of pliability of the gastric wall This condition is most frequently found in patients having an alcoholic history, or those showing a tendency to sclerotic changes in other organs

SUMMARY

1 The types of stomachs may be divided into four classes to facilitate indexing

2 The motor phenomena of the stomach are complex, showing a gastric cycle, consisting of a systole and diastole, and the progression toward the pylorus of peristaltic contractions

3 The appearance of the cap (first portion of the duodenum) is a vital factor in gastroduodenal diagnosis

4 The second and third portions of the duodenum may be artificially dilated

5 The lesions which can be diagnosed by serial radiography include carcinoma, hour-glass constriction, adhesions from gastric ulcer, duodenal ulcer, and gall-bladder infection, with or without calculi, dilatation from obstruction or atony, and atrophic contraction

6 The radiologist can recognize and differentiate between these conditions with about the same degree of certainty as can the surgeon at an exploratory operation without the microscopic examination of the specimen

103 Park Avenue

ABSTRACT OF DISCUSSION

Dr G E Pfahler, Philadelphia I think that it is a waste of time to attempt to classify these types, they are not definite enough for classification One shades into the other so gradually that any attempted classification means nothing We should be very careful in our endeavors to draw certain conclusions More fluoroscopic work should be done and I do not believe that we should attempt to depend on the cinematograph in drawing so many conclusions The systole and diastole of the stomach have not been shown on the fluorescent screen and I do not believe that so much confidence should be placed on what these serial photographs reveal

Dr. Lewis Gregory Cole, New York The types of stomach were simply used for classification, and have no relation to the function or pathology of that organ Diastole and systole of the stomach are shown more or less distinctly in nearly every series of stomach radiographs, and as each radiograph is an accurate representation of the lumen of the stomach at the instant it is made, there can be no doubt of its presence If I have conveyed the impression that there are two sphincters, I wish to correct it There is but one sphincter, and that separates the cap from the pyloric end of the stomach, and may be studied carefully in the radiographs If this detail is not visible on the screen, it proves that fluoroscopy is not so accurate as radiography

Economic Importance of Mental Diseases—The amount appropriated for the care of the insane during the past year in New York was 23 per cent of the total expenditure of the state Compare this with the other fields of state expenditure education, 24 per cent , public works and conservation 13 per cent , prisons and reformatories, 4 per cent , the legislature, 4 per cent, the militia, 2 per cent , health and quarantine, 1 per cent , and care of all other wards of the state, such as the epileptic, feeble minded, blind, crippled, disabled soldiers and sailors, 8 per cent To the layman these startling figures must give some impression of a fact which some scientists and physicians deeply realize, namely that modern civilization must take hold of the problem of insanity with vigor, energy and scientific skill The hopeful thing about what appears to be on the surface a situation of despair is that insanity is not, as our forefathers used to believe it to be, an "act of God," but is a disease which can to a very large degree be prevented and to a considerable degree cured by mental and physical hygiene —*The Outlook*

THE ORIGIN OF TUBE-CASTS

H. B. ERDMAN, M.D.
First Assistant Physician State Asylum for Chronic Insane
WERNERSVILLE, PA.

Tube-casts are formed in most, if not all, conditions of kidney deterioration. To a limited extent also, they occur apart from other evidences of deterioration. This fact, bearing on the diagnosis of early renal disease, warrants a close study of their origin and significance.

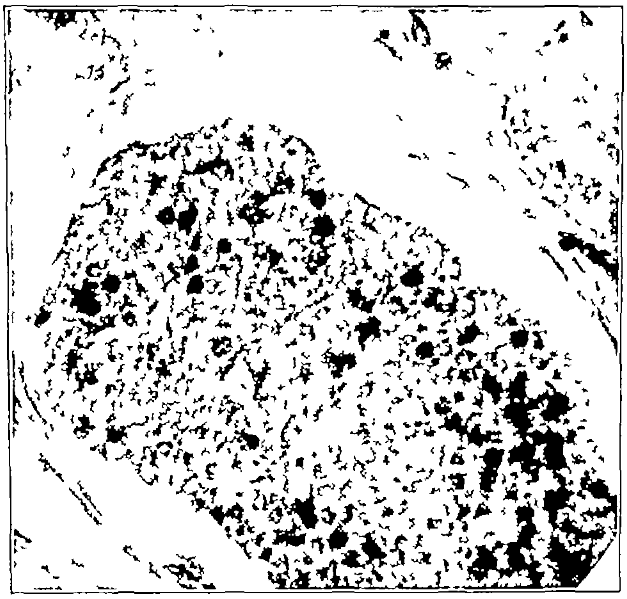

Fig. 1.—First stage waxy cast: hemorrhage into tubule with distention by blood-clot.

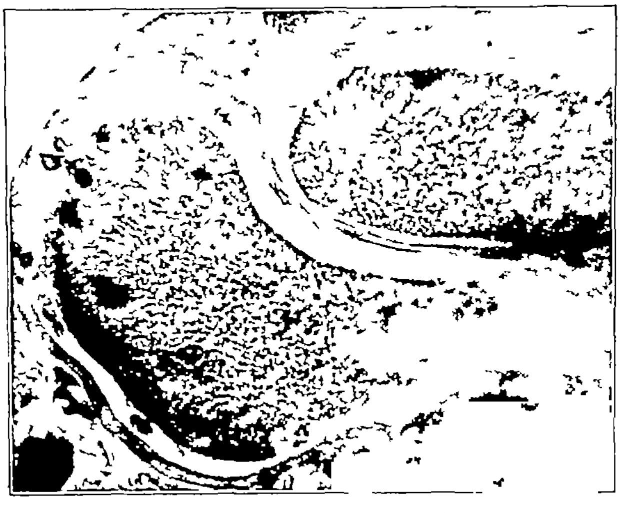

Fig. 2.—Second stage waxy cast: blood coagulum undergoes granular disintegration. Note compression of tubular epithelium.

The literature on the subject discloses many divergent views, of which even a partial review cannot be given. The objects here intended are to consider certain primary differences in casts and to account for their origin.

Tube-casts may originate from a number of the materials entering into the structure and composition of the kidney and blood, unchanged chemically and morphologically, or broken down and altered by processes of degeneration or by the action of the urinary secretion. It is evident therefore that uniformity of composition cannot be looked for. The protein units forming cellular matter are complex and subject to great variations, and so also are the products of waste and destruction. No attempt will be made to take up the chemical composition of the materials to be described, since whatever the composition, their derivation must be determined largely on morphologic grounds.

Tube-casts may be divided into three main groups: hyaline casts composed of an acid protein similar to mucin and nucleo-albumin; granular casts allied to albumin and cytoplasm; and waxy casts consisting mainly of altered blood coagulum. In addition to these materials there are fixed and wandering cells, erythrocytes, fat globules and crystals of various sorts.

The kidney has for a long time been the favorite organ for the study of granular degeneration. Present views tend to regard cell protoplasm as an emulsion of protein granules, which during degenerative processes become aggregated into more visible particles. At first the granules can be cleared with dilute acetic acid, later, however, a true coagulation takes place and they are no longer soluble. An early and a later stage are therefore distinguished.

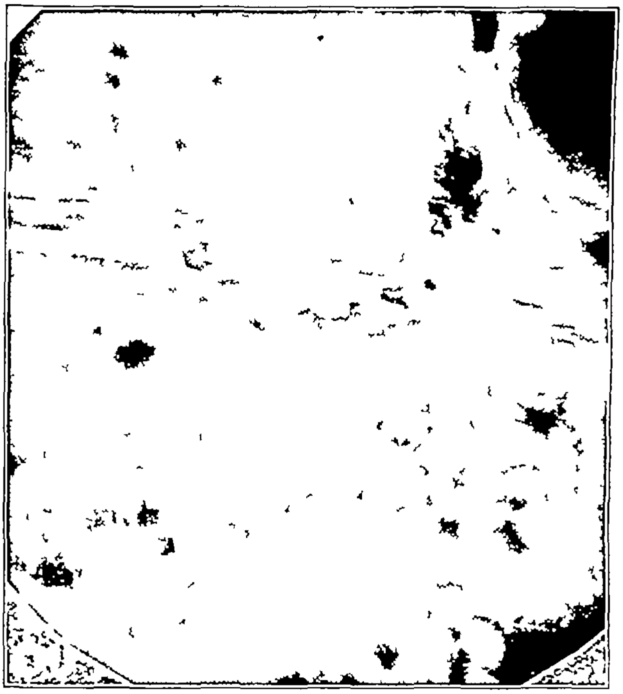

Fig. 3.—Final stage waxy cast. Cast becomes homogeneous. Vacuoles appear on surface.

The early stage can be regarded as not more than a physiologic response to stimulation,[1] and is compared to the secretion of mucous or albuminous glands. Fine granules appear along the margin of the cell bordering on the lumen, where they are dissolved or extruded, and the cell retains its integrity. The granules thus derived become more gelatinous in their descent, change in reaction and finally emerge as hyaline material. As there are other forms and sources of hyaline material,[2] reference is here made only to that found in hyaline casts. Many substances formerly regarded as having no visible structure are found in fact to be composed of fine granules, and hyaline casts likewise, when examined under high amplification in a suitable light, exhibit many transparent particles.

---

[1] Wells: Chemical Pathology.
[2] Hammersten and Mandel: Physiological Chemistry.

The late stage of parenchymatous degeneration terminates in destruction of cell nucleus and protoplasm. The necrotic mass descends, forming granular casts, or also is transformed into hyaline material,[3] the essential factors being clearing of the granules and change to an acid reaction.

Hyaline casts therefore can be produced through both early and advanced cell changes, but to these sources must be added the probable origin of hyaline material from albuminous serum exuded by the glomerulus, and transformed in the tubules by certain acid principles in the urine, the change being only physical, or both physical and chemical. The assumption is made that hyaline casts are not usually associated with destruction of the parenchyma. This is taken from the fact that hyaline material is found in normal urine in other forms than casts, being commonly, though incorrectly, termed mucus.

HYALINE CASTS AND ALLIED BODIES

Mucus, so called, the basis of hyaline casts is a normal constituent of urine. The amount of mucus is increased in urine of high specific gravity, in urine of high acidity, in venous congestion, in toxemias from infectious diseases, digestive disturbances and irritant poisons, in some forms of nephritis, in cystitis, pyelitis and irritative and inflammatory conditions of the genital organs. Not all the mucus or mucoid substance found in urine comes from the kidney. Mucus derived from the kidney is seen in long strings ranging from threads of extreme fineness to broader bands and ribbons, often there are branched filaments or numbers of agglutinated threads arranged longitudinally, spirally or otherwise. The term "cylindroid" has been applied to the broader cast-like formations, differing from casts only in compactness, and in not entirely having filled the tubules in which they were molded.

The material forming hyaline casts seems to be identical with that in mucous threads,[4] and casts are very commonly seen pinched off at one or both ends into a fine thread. Casts are produced by a retention of the hyaline material in a tubule which often becomes dilated, and therefore the width of the cast does not indicate the part of the kidney from which it comes. The tubules of the kidney are subject to sharp changes in direction and at such places are more prone to obstruction. The tubule behind the obstruction dilates until sufficient pressure is established to force the cast through. Hyaline casts are usually molded in the limbs of the loop of Henle, where the material in a fine stream entering a tubule of wider caliber often coils itself spirally. Many hyaline casts are formed spirally, the structure showing itself as an occasional notch in the side of the cast, and such casts are sometimes termed convoluted, implying formation in the convoluted tubules which is not the case. Mucus maintains its viscous colloid state only in solutions of sufficient concentration and acidity, dissolving in pure water and in alkalies. Hence urine of low specific gravity and alkaline urine contain little formed mucus.

GRANULAR CASTS

Parenchymatous degeneration attacks the cells of the convoluted tubules with great intensity, where the granular and necrotic material accumulates in the lumen until discharged. Granular casts as seen in urine usually have a basis of hyaline material in which the granules appear as scattered points, or again the whole cast is composed of granules. Granular matter takes the protoplasmic stains, with special affinity for fuchsin.

Granular casts may also be of exudative origin and as such cannot be distinguished from the degenerative kind. They are found in large number in the exudative forms of nephritis. Granular exudation is seen typically in the capsular space.

A third form of cast arises from granular disintegration of blood coagulum, as will be described under waxy casts. These casts are composed of dark, deeply staining granules not likely to be distinguished from dense degenerative or exudative granules.

Fatty globules when found in casts often accompany epithelial cells or their fragments. They are regarded either as an infiltration or a degeneration, in the latter case belonging to the lipoids.[5]

WAXY CASTS

The typical waxy cast is an altered blood coagulum, the result of hemorrhage into a tubule. Hemorrhage may come either from the glomerulus or directly through the injured wall of the tubule. The blood fills the tubule, occludes its distal end and often greatly distends its walls, until the epithelium shows as low flat compressed cells. The clot entirely fills the lumen of the tubule, when seen in kidney sections, however, the cast has contracted owing to the action of dehydrating agents and appears to lie loosely in the tubule.

First are seen the red corpuscles in their usual form, next they undergo granular disintegration and finally fuse into a solid cast. Sometimes the leukocytes are seen drawn together into a clump.

Waxy casts appearing in the urine are generally not of great length, are tortuous or of the corkscrew variety, and are true molds of the convoluted tubules, differing in this respect from spiral hyaline casts. Occasionally waxy casts are long and straight. Possibly there are instances in which waxy casts are formed by the fusion of granular epithelial matter.

The production of waxy material from blood likewise takes place in the capsular space where it is seen lying in half-moon shape, or even involving the glomerulus when there is hemorrhagic destruction of the tuft. Waxy casts do not denote amyloid disease of the kidney.

Red cells leaving the tuft in small numbers become swollen in the capsular space, exhibiting a few scattered granule-like points, and enter the convoluted tubules where they disintegrate. This condition is sometimes seen when the glomerulus shows no other change.

As far as this work has gone, I am led to believe that tube-casts of all kinds except epithelial and fatty, more frequently come from the protein elements of the blood, through temporary or permanent insufficiency of the glomerulus, than from the tubular epithelium. Leaking of the tuft during periods of hyperemia does not imply serious injury to the thin-walled capillaries. Occasional traces of albumin in the urine are not incompatible with good health.

The chief varieties of casts having been outlined it needs only to be briefly stated that frequent combinations are entered into with epithelial cells, leukocytes and red cells.

[4] Coplin, W. M. L.: Microchemical Reactions of Tube-Casts, Philadelphia Med. Jour., March 8, 1902.

[5] Oertel: The Anatomic Histologic Processes of Bright's Disease.

The diagnostic value of polynuclear leukocytes is often exaggerated Scarcely an average urine can be examined without finding definite numbers of free leukocytes, and increased numbers occur from only the mildest irritations of any part of the genito-urinary tract Little reliance can be placed on leukocytes in the diagnosis of nephritis unless they are incorporated in casts, or else are obtained by catheterization of the ureter

Mononuclear cells of slightly larger diameter are more likely to come from the kidney, it is not safe to term them "epithelial cells," however, because they are usually wandering cells which occur in large numbers in nephritis[6] These cells often have dense deeply staining protoplasm, and can be found coming from glomeruli undergoing destruction, which no doubt is only one of a number of sources By some they are held to be phagocytic

The process of nephritis probably involves all the structures of the kidney, in no case affecting either the parenchyma or the interstitial tissue alone, however great variations occur in the intensity and duration of the process, and these factors are responsible largely for the different types The regenerative power of the kidney is great Restoration follows nephritis of considerable intensity from acute infections, even in more advanced cases there is marked and prolonged power of the kidney to adapt itself to conditions

In estimating the value of casts, we should bear in mind that the kidney is subject to normal wear and that periods of exaggerated waste of kidney tissue may exist at times without exceeding the limits of repair, also that as age advances slight kidney changes are more apt to occur, these often being focal, or involving only small parts of tissue, such as in the senile and arteriosclerotic kidneys

Tube-casts give no reliable information as to the functionating power of kidney It is natural to infer that their presence in the tubules is a hindrance to free excretion, though to what extent this may be the case is yet to be determined On this point more can be learned by careful continued observation on the excretion of water, chlorids and urea, and on the phenolsulphonephthalein output which has been estimated by me in series of cases attesting to its usefulness as claimed by the originators[7]

PRESENT STANDING OF THE OPERATION OF LITHOLAPAXY *

ARTHUR T CABOT, A.M., M D

BOSTON

To our knowledge of the very perfect operation of litholapaxy I can contribute nothing important Indeed, I can add but little to what I said about it in 1899 before the Section on Surgery and Anatomy of the American Medical Association[1] at Newport

At that time I stated my opinion that litholapaxy was the operation of choice for the removal of most stones in the bladder After a much enlarged experience I wish to express the belief that litholopaxy is the operation of choice in all uncomplicated cases of stone and having seen this opinion constantly supported and confirmed by such masters of genito-urinary surgery as M Guyon, Freyer, Keyes, Keegan, Chismore and others, it has been a source of surprise to me to find the operation imperfectly understood and little practiced among the younger generation of surgeons

So great has seemed to me the indifference toward this operation even among some of the men who are devoting themselves to the special work of genito-urinary surgery that I am glad of this opportunity to endeavor to bring about a better and more intelligent opinion of this safe and satisfactory operative procedure

Why do surgeons pass by this operation (litholapaxy) having a mortality of from 1 6 to 6 per cent, according to the age of the patient, and resort to one (suprapubic lithotomy) having a mortality of from 10 to 20 per cent ? It is not because the more dangerous operation has a shorter and easier convalescence, for after suprapubic lithotomy convalescence is more painful and from four to ten times as long as after litholapaxy Again, litholapaxy interferes less with the functions of the bladder, and in my experience of 219 cases of stone removal there has been more tendency to recurrence after suprapubic cystotomy than after litholapaxy

The advocate of suprapubic lithotomy will say that when the bladder is opened, unsuspected conditions are sometimes found which require the suprapubic opening for their proper treatment In the early — what I may call the blind — days of bladder surgery, this had a certain amount of truth and justification in it, but at this time when the cystoscope gives the operator ample opportunity to become acquainted with the interior of the bladder before deciding on the operative procedure, it is no longer justifiable to subject all patients with uncomplicated stone to a more serious and dangerous operation in order to avoid occasionally overlooking some complication

There is, then, no good reason to be advanced in favor of the suprapubic operation in uncomplicated cases, and yet many men continue to practice it and subject their patients to needless risks and discomforts This is so, in my opinion, because many surgeons are not provided with the necessary instruments, and they have never taken the trouble to inform themselves and to be instructed in the technic of the crushing operation

A litholapaxy outfit, while not very expensive, is a considerable addition to a surgeon's armamentarium, and may seem a serious burden to a general surgeon who sees comparatively few cases of stone When patients with stone go to surgeons not equipped for litholapaxy, the question may be asked how these surgeons meet the situation

They know that even after suprapubic incision the mortality is not very high and they wish to operate themselves rather than turn the case over to a rival, expert in lithotrity They do not make a close enough analysis of the situation fully to realize that by this course they are subjecting their stone patients to a mortality risk fully 10 per cent higher than is justifiable From their point of view their position is strengthened and justified by the belief that there is unusual danger attaching to litholapaxy to be overcome only by unusual skill

This idea of unusual difficulties surrounding litholapaxy is wholly exaggerated and only to be accounted for by lack of familiarity with the operation and its results As a matter of fact, the skill required in the use of the lithotrite is no greater than that needed in an ordinary cystoscopy, and no surgeon is competent to undertake bladder surgery who is not competent to use a cystoscope. Inexperience adds no more to the danger of litholapaxy than it does to the danger of suprapubic cystotomy. Furthermore, my opportunities for seeing young surgeons undertaking their early litholapaxies have convinced me that a litholapaxy in inexperienced hands is less dangerous to life than a suprapubic cystotomy in the hands of an experienced general surgeon, because the intrinsic dangers of the operation are much less.

[1] Cabot Arthur T The Choice of Operation for Stone in the Bladder THE JOURNAL A M A Nov 9 1899 p 657

The fear felt by inexperienced surgeons for the lithotrite is therefore unfounded. A brief study of any of the more detailed descriptions of the operation will fit a man with any training in urethral manipulations to perform the crushing operation safely. The instruments are simple and any one who uses urethral instruments with gentleness and care can readily manage them.

This is no time or place to discuss at length the fine technical points of the crushing operation. The one thing of importance is that the bladder be moderately distended before the lithotrite is introduced. If this is done it is practically impossible for the bladder wall to be caught between the jaws. The fear of this accident seems wide-spread and yet I never knew of any damage being caused in this way.

Formerly, before the modern treatment of prostatic hypertrophy was developed, it was a common thing in my practice to crush stones behind greatly enlarged prostates. The operation was often carried out in a distorted bladder and the instruments were manipulated through a stiff and tortuous urethra. I have notes of 185 cases in which a formal litholapaxy was done under general anesthesia and I have not included a large number of cases in which small stones or calcareous gravel were pumped out with or without local anesthesia. Notwithstanding the unfavorable conditions under which many of the earlier operations were performed only eight patients died, a mortality of 4.32 per cent.

To understand fully the degree of responsibility of the operation for this mortality it is well to glance a moment at the fatal cases.

Case 1.—A woman of 62 with extensive tuberculosis of the glands died one month after a combined litholapaxy and curettage of the cervical glands. The bladder had fully recovered. Death resulted from general cachexia.

Case 2.—A man of 84 died one month after litholapaxy of sudden pulmonary embolism.

Case 3.—A man of 69, feeble and with a chronic bronchitis, underwent an easy operation. The urine was clear and bladder irritation disappeared the first week. On the tenth day the patient died of pneumonia.

Case 4.—A man of 70, with complete obstruction in prostate and suppression of urine, was operated on in the country as a desperate effort. The kidneys never resumed work, and death ensued in twenty four hours.

Case 5.—A broken down man of 60 with chronic bronchitis and a weak heart had bladder tenesmus. On account of the patient's wretched general condition he was kept under treatment for almost two months. Pain prevented improvement. A quick litholapaxy was finally done as a desperate measure to give him relief. Difficulty of respiration was greatly increased, and death followed three days later.

Case 6.—The patient was a man of 70 who had suffered with symptoms of stone for fifteen years. After litholapaxy there was good recovery from bladder symptoms. Then hematuria set in and in my absence another surgeon opened the bladder but found nothing. After death the kidneys were found full of stones.

Case 7.—A man of about 70 was operated on at a hospital in a neighboring city. A catheter was fastened in after the operation, as it was a prostatic case. I had no notice that things were not going well until I accidentally heard of the patient's death.

Case 8.—A man of 70 underwent an easy operation, but he died and autopsy showed hydronephrosis and pyelonephritis.

Of these eight deaths then, two occurred a month after operation as a result of conditions not connected with the litholapaxy. Two other deaths were caused by pneumonia consequent on the anesthetic in patients with chronic bronchitis, and one patient was in a desperate condition from acute suppression of urine. In view of these facts I think it will be conceded that even the low mortality of 4.3 per cent. was not wholly to be laid at the door of the operation. Among uncomplicated cases of stone there were no deaths.

Modern surgery rightly demands that in cases of prostatic obstruction with secondary stone, treatment shall be given for the obstruction and that the removal of the stone shall be merely an incident in the operation for removal of the prostate. Whether the surgeon elects the perineal route or the suprapubic for the removal of the prostate, the stone is easily removed by either without added danger.

This change in the method of treating secondary stones behind enlarged prostates has taken from the accepted domain of litholapaxy most of the cases of real difficulty in manipulation, the cases among which the slender mortality occurred, and for the crushing operation are left the uncomplicated cases which have practically no mortality and those occasional prostatic patients who shrink from the added risk of a prostatectomy and find themselves comfortable when the stone is removed.

Since Dr. Bigelow published to the world the operation which he named litholapaxy there have been few changes in the technic. Dr. Chismore's evacuating lithotrite is perhaps the most considerable and important innovation which has been brought forward. In the hands of its distinguished inventor the evacuating lithotrite did extraordinarily good work. Dr. Chismore operated usually without general anesthesia and was content to do an operation in several sittings when that was necessary. With a conscious patient the evacuating lithotrite had the distinct advantage that the suction of the pump drew the fragments between the jaws. The lithotrite therefore did not have to be moved about in search of fragments and the operation was consequently less painful.

In my experience with Dr. Chismore's instrument the small size of the evacuating tube has been a decided disadvantage and I have come to use the instrument only occasionally, when the search after a last elusive fragment has been troublesome. The combination of a cystoscope with an evacuating lithotrite is a last refinement devised by Dr. George Walker to facilitate the search for a last fragment.

It must be difficult at the end of a crushing operation to obtain a clear medium in which satisfactory cystoscopic manipulations can be carried out. In all of my series of cases I never had more than a momentary difficulty in seizing the last fragment, this difficulty was met only in sacculated bladders behind enlarged prostates — in cases which are not now selected for litholapaxy.

In this article I have endeavored to indicate the change in the status of the operation of litholapaxy that has come about since my former paper in 1889. We have seen that modern prostatectomy has taught a better way of disposing of the troublesome class of cases that furnished most of the difficulties met by the early lithotritists Having emphasized this additional exception in which a cutting operation should be preferred to litholapaxy, I shall close by repeating the assertion made in that earlier paper

> In my opinion, we have in litholapaxy the operation of choice for the removal of most stones While this is the rule, there are exceptions to it, and the varying conditions surrounding stone in the bladder will now and then lead us to choose some other operation for their safest removal
>
> The surgeon who best appreciates these varying conditions, and selects in each case the operation which most surely avoids the dangers surrounding "that particular patient," will arrive at better results than any advocate of a special operation, however expert

SUPRAPUBIC CYSTOTOMY FOR VESICAL CALCULUS

INDICATIONS AND OPERATIVE PROCEDURE *

WILLIAM E LOWER, M D
CLEVELAND

There are but two operative methods now considered practical for the treatment of stone in the urinary bladder One is the crushing of the stone and the removal of the fragments through the urethra, the other is the opening of the bladder suprapubically and the removal of the stone through the incision.

He would be obdurate indeed who did not acknowledge the wonderful invention of the lithotrite and the achievements accomplished by its inventor At a time when any cutting operation carried with it such a high mortality and the convalescence was so prolonged in those who survived, the lithotrite, with the skilful touch of Bigelow, was truly a blessing, but the conditions that prevailed then with regard to the cutting operation no longer exist to-day Little advancement, if any, has been made for the crushing operation, while each year brings a better record for the suprapubic operation

To say that either operation should be used to the exclusion of the other for all cases of stone in the bladder would be ill-advised, but the cases generally recommended for the use of the lithotrite by the advocates of litholapaxy are, as a rule, selected cases and naturally would have a lower mortality-rate, no matter what kind of operation Surgery is rapidly turning from the dark to the light, and blind operations or those depending entirely on the sensation of indirect touch must be replaced, wherever possible, by operations conducted by inspection of the field or by the direct aid of the fingers We all know that it is possible by large experience to become fairly accurate by indirect palpation, but it can never be so nearly exact a method as that which depends on seeing or direct feeling

The opportunities for any one person in this country to acquire a large experience with the lithotrite within any reasonable time are very limited, material in clinics is not sufficient to give the student the practical experience necessary to do a successful litholapaxy, and certainly no one would recommend its use by the untrained, while the opportunities for teaching suprapubic opening of the bladder are quite common, there being many other conditions besides stone for teaching this technic In India where so large a proportion of natives have vesical calculi, an extensive experience may be acquired in a comparatively short time, as most statistics for the lithotrite come from India, the comparison is hardly fair

Most advocates of litholapaxy admit that the stone should be freely movable, that there should be sufficient bladder capacity, and that the urethra should be of sufficient size, also that a very large prostate, an encysted stone or a stone with a foreign body as a nucleus are all contra-indications to the successful use of the lithotrite For these more or less difficult cases suprapubic cystotomy is recommended If, then, the mortality-rate should be somewhat higher for the cutting operation would the comparison be fair?

Among the causes mentioned as being responsible for deaths in suprapubic operations is peritonitis This should no longer occur, for with better aseptic methods and better technic the dangers of peritonitis are reduced to a minimum Better local and general anesthetics have reduced the danger of shock from the operation, and better methods of dealing with the wound have shortened the period of convalescence and reduced the complications to a minimum

The complications and mishaps of the lithotrite, when they do occur, are nearly always serious I am treating now a most persistent stricture resulting from the use of the lithotrite by a colleague In this case there had been an extensive laceration of the urethra

INDICATIONS FOR SUPRAPUBIC CYSTOTOMY

Overenthusiastic exponents of litholapaxy may make the statement that they have never seen a stone too large or too hard to be grasped by the lithotrite, but their experience is scarcely borne out by the experience of other surgeons or by the many reported cases in medical literature Even in the special stone number of the *Indian Medical Gazette* expert operators confess that this condition does exist The case reported by Richards[12] is a good illustration The stone weighed 2 pounds, lithotrity failed, perineal incision failed because the stone had to be chiseled, and the stone was finally removed suprapubically, the wound healing readily In my own practice there have been eight cases with large hard stones which I feel could not have been removed without great difficulty by any other than the suprapubic route The patients made quick recoveries without complications

The operative treatment of encysted or adherent calculi is always the high incision, as the many published cases prove Inspection is absolutely necessary here I have had three such cases, in one a stone about 2 cm in diameter was enucleated from a pocket in the region of the trigonum, only the very tip showing In another the stone was firmly adherent behind the prostate In the third case cystoscopy showed a calculus embedded in the mucous membrane over the right half of the trigonum This case is of further interest in that the patient returned in six months complaining of the old trouble, cystoscopy showed the diverticulum at the site of the former stone Again suprapubic incision was made, several soft stony deposits removed and the diverticulum dilated, since which time the patient has been in good health

Where multiple stones are present the superiority of the suprapubic method is hardly to be doubted, for exposure of the operative field is necessary for a thorough search. In my practice I have had ten cases of multiple calculi, in one of which I removed ninety-three stones, six the size of filberts and eighty-seven ranging down to the size of a grain of wheat, there was extensive trabeculation This patient was 84 and made an uninterrupted recovery

* This article is abbreviated in THE JOURNAL. The complete article appears in the Transactions of the Section and in the author s reprints.

[12] Richards Lancet London, 1908 ii 230

The suprapubic operation is generally accepted as the operation of choice in the young The operations of Milton[7] and Assendelft[9] are good proof of the wisdom of this Even Thompson did not advise litholapaxy in children My youngest patient was a 19-month-old baby There was a quick convalescence

The presence of calculi in old men is another indication for the suprapubic incision Thomas,[13] in an article on calculus in old men, gives the histories of four cases in which the calculi were so situated behind the prostate that the lithotrite could not grasp them The stones were removed suprapubically and the patients made good recoveries My seven patients, all over 70, left nothing to be desired so far as operative recovery was concerned

Except in the hands of the most experienced, prostatic hypertrophy offers obstruction to the lithotrite, there being few surgeons who will not prefer the suprapubic method Six of my patients had marked prostatic hypertrophy, on three of whom I performed a prostatectomy at the same time

The location of the calculus projecting from the vesical end of the ureter is another indication for the suprapubic method I have had several very interesting cases of this kind, also two cases in which the stone was wedged in the neck of the bladder and considerable force was necessary to dislodge it It could hardly have been removed in any other way

The presence of a foreign body as a nucleus is another hindrance to crushing Many such cases are on record My cases of this kind are three in number, the nucleus being a hair-pin in one case, the wick of a taper about 3 inches long in another, and a piece of wax in the third Calculi associated with tumor also hinder crushing and a strictured urethra almost necessitates the cutting operation

A recent case in my practice was of more than general interest The patient, a man aged 67, suffering from severe ascites and marked myocarditis, was in almost continuous pain, due to a bladder contracted firmly about a very rough stone There was practically no bladder capacity Five liters of cloudy serum were drawn from the abdominal cavity the day before the operation Under nitrous oxid and local anesthesia, a large calculus was successfully removed suprapubically

The reports of Lakeside Hospital, Cleveland, for the ten years from 1900 to 1910 show forty-six operations for vesical calculi, thirty-eight were done suprapubically, seven were litholapaxies and one was removal of the stone by dilatation of the urethra Four deaths occurred in the suprapubic cases, all four being complicated cases One man of 68 had acute double hydronephrosis, another of 74, with a very weak heart, had a prostatectomy at the same time, the third had marked prostatic hypertrophy and the bladder was divided into two compartments by a small band, the fourth patient, a man of 55, showed a gelatinous condition of the bladder mucosa, the bleeding being a constant oozing The mortality of the suprapubic operations was 10 5 per cent One death occurred in the litholapaxies, that of a boy of 12 who died from severe laceration of the bladder The mortality of the litholapaxies was 14 28 per cent

One of the objections to suprapubic cystotomy is the prolonged convalescence This was a valid objection when the bladder was drained, but it is no longer necessary to drain the bladder after removal of stone or tumors If the bladder is properly closed, a week or ten days is all the time necessary for a complete cure I have been closing the bladder in practically all suprapubic operations, with the exception of suprapubic prostatectomy, and have more than 90 per cent of primary unions

For the success of this operation certain points in the technic, which I have described in a previous paper, are necessary In brief they are as follows The cut edges of the bladder should not be grasped with crushing forceps The edges must be carefully approximated while the wound is on the stretch so that the stitches will not be separated when the bladder is distended with urine The ligature must be absorbable My personal experience consists of fifty-three suprapubic operations for stone in forty-nine cases, with no deaths There were four cases of recurrence Good recoveries resulted in all cases Two of the forty-nine patients were women Three patients were below 15 years of age, sixteen between 15 and 50, twenty-nine between 50 and 84 The youngest patient was 19 months, the oldest, 84 years The average age was 53 4 years In thirty-three cases the bladder was immediately closed, leakage occurring in only three cases and in two of these only a small amount, and for a short time

Until a practical observing lithotrite is invented, which will give the operator the opportunity of seeing the field of operation, suprapubic cystotomy for stone must remain the method of choice by the majority of operators

1021 Prospect Avenue

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS CABOT AND LOWER

Dr John Myers Swan, Canton, China In the Canton Hospital of South China, during the last twenty years I have had 1 058 lithotomy operations for urinary calculi, 950 of which were by the old lateral perineal section and about fifty by the suprapubic In addition to that and during my earlier experience in the treatment of this disease, I had to deal with about 258 by litholapaxy There are two or three factors that have caused us to adopt the operation we have generally done first, the age of the patient Out of 1,058, 330 were under 10 years of age, and we all know that it is not nearly so easy to use a lithotrite in patients under 10 years of age as it is in the adult The factor that first influenced me with regard to the operation best to do was the mortality rate My predecessor, Dr John G Curry, was one of the most famous lithotritists in his time, and we have in the hospital one of the best outfits for lithotrity In the first few years of my experience the mortality rate ranged higher in the operations for litholapaxy than in the ordinary lithotomy The second and perhaps the most important factor was that there was recurrence after litholapaxy Dr John G Curry was a skilled lithotritist, and yet I have found that anywhere from six months to a year and a half after litholapaxy our patients returned with recurrent stone Recurrence very rarely occurs after lithotomy Third, when we have from ten to twenty operations in one day, the question of time must be considered From two to five minutes from the time the patient is anesthetized until he is ready to be removed from the table will generally allow of a lithotomy Lithotrity cannot be done in that time. The advantage to the patient, the liability to return after litholapaxy, and the quickness, ease, convenience and safety of the operation, have influenced us to adopt lithotomy, either suprapubic for the larger stones, or the ordinary lateral perineal for the smaller ones Exclusive of serious organic disease, aside from kidney or bladder, our mortality rate after lithotomy, either suprapubic or perineal, has been reduced to 3 per cent, and in one single year I did sixty two perineal and suprapubic sections with no mortality

---

[13] Thomas Lancet London 1900 1 1652.

Dr A. L. Chute, Boston I do not know whether you are all aware that Dr Cabot was the pupil and great friend of Dr Bigelow, our surgical primate of Boston, who, we think, did so much in establishing this operation In spite of the statistics from Canton, I do not see how anybody can hold to the cutting operations It seems to me that the operation of litholapaxy is so much easier In uncomplicated cases it does not seem to me that we ought to consider the suprapubic operation from the point of view of the patient I disagree with Dr Swan as regards the time That is not an argument It is the surgeon's time as compared with the patient's convalescence

Dr Hugh H. Young, Baltimore I hesitate to say anything when there is a man present who has done 1,058 stone operations, an appalling experience to the rest of us I agree with Dr Cabot and Dr Chute in the thought that it does seem a shame in this day of the cystoscope to do a cutting operation for stone in the bladder in uncomplicated cases, when it is so easy to crush this foreign body Of course there are reports of a few cases of rectal fistula and a certain number of cases of incontinence in which the lateral perineal operation has been employed, so that the English surgeons in India have practically given up either the median or the lateral lithotomy We have all seen severe suprapubic infections, and occasionally extravasation One of my patients died from interrectus infection following the removal of a calculus The fact that these complications are not possible after the litholapaxy operation ought to lead us to try wherever possible a crushing operation Litholapaxy has fallen into disfavor on account of the length of time consumed, and on account of the difficulty in finding the last fragment which often remains and leads to the recurrence of stone

Chismore was right in trying to perfect the operation by changing the instrument so that the stones could be sucked into the blades, caught there and crushed without hunting all over the bladder for them Those of you, however, who have tried Chismore's instrument know of the difficulties It was mechanically not a well constructed instrument One could not handle it so quickly and easily as the Bigelow The evacuating tube was so small that it was impossible to get anything except the small fragments through it, although I think that the evacuating principle was a good one Therefore, I constructed a lithotrite, fashioned after Bigelow's principle, with the handle hollow, a stop cock and an evacuator attached to the instrument, thus making it possible to have an assistant work the evacuator while the surgeon is crushing Then, if desired, it is easy to introduce a straight cystoscope through the instrument, hunt for any fragment, pick it up and crush it There are certain difficulties in the perfection of this instrument which have made me hesitate to put it on the market The difficulty is in the balancing of the metals, to have the blade large enough and strong enough, whether the old Bigelow blade or a fenestrated posterior blade is used Freyer and Keegan have shown that pushing of fragments through the fenestra does no harm A fenestrated posterior blade makes a more effective crushing instrument than Bigelow's blade So my instrument which is made after the principle by Leiter has the fenestrated blade It seems to me that the great trouble with the lithotrite is the introduction of one instrument after another and the hemorrhage that results from the passing of the instruments through the posterior urethra With an instrument introduced only once there is practically no bleeding, so that cystoscopy is really quite practicable

Dr Louis E. Schmidt, Chicago I should like to draw attention to the phrase, 'enlarged prostate complicated with stone" which seems to be a general term I am quite sure however, that if we use the cystoscope, we can often readily see that we are dealing with a primary stone, and that the prostate has absolutely nothing to do with the condition In the past three years I have crushed stones in three patients over 65 years of age All had been advised to have a prostatectomy and naturally removal of the stone In all three instances litholapaxy has given perfect results I think that it is well worth taking into consideration that it is the stone that is causing the trouble and not the prostate, and that we must not always think that the prostate has to be removed with the stone

Dr Eugene Fuller, New York I have always felt that there was a very large and useful field for litholapaxy There is no doubt that it is an operation which requires great dependence on the sense of touch, and if a surgeon has that accomplishment, he will find in many cases that it will be the simplest thing in the world to crush a stone and to remove it, by so doing he will subject his patient to less danger and pain than by cutting There are cases in which stone is only secondary to some other condition, and of course, one does not want to try to crush I think that is the case in a great many conditions of the prostate, not all of them, as Dr Schmidt has just pointed out For instance, if a phosphatic stone is secondary to foul urine in the postprostatic culdesac, there is little use in trying to crush that stone and leave the foul urine It is better to remove both the prostate and the stone If there is a hard stone and a clean bladder in a condition of prostatic retention, then it may be worth while to crush the stone One curious point that is brought up sometimes is the tolerance to stone One sees a certain class of cases in old men who have an extreme amount of tolerance, in such cases, for instance, there exists a mulberry calculus of the roughest kind with perfectly clear urine and no pain. The only way I can explain that condition is that these men have so much prostatic obstruction that the stone during urination lies in the culdesac and consequently is not brought into the grip of the neck of the bladder at the end of the act I have never seen a young man who harbored a stone like that without a great deal of pain in the bladder

Dr George S Whiteside, Portland, Ore I have just seen the large collection of stones from the Canton Hospital here on exhibit They are a most wonderful collection and some of them could not have been crushed Some are as big as paving stones Conditions are a little bit different in this country from those in Canton, and it seems to me that we see the smaller stones Educated people, when they have anything the matter with them, go to see a physician instead of waiting until the stones are large Here, litholapaxy is better than any cutting operation It keeps the patient in the hospital but twenty four hours, and the number of cases of recurrence that one sees after litholapaxy, with a proper cystoscopy afterwards, is almost *nil* In neglected cases with large stones a cutting operation is often preferable

Dr William T Belfield, Chicago In nearly a hundred of my operations for stone, calculi were removed neither by crushing nor suprapubically, but by a simple median urethrotomy I have no doubt that had I been brought up in the classic shades of Harvard I should have removed some of these by a crushing operation But median urethrotomy gives advantages which litholapaxy cannot furnish, that is, drainage of the bladder, with less danger than a suprapubic operation So I think we should not allow to go unchallenged Dr Lower's statement that there are but two practical operations for stone in the bladder

Dr A. T Cabot, Boston Our experience in litholapaxy in children in this country, of course, is nothing as compared with the experience that they have in China and India, but against the remarks just made by Dr Swan we must remember the remarks of Keegan and Freyer They operated among a similar clientele, had an enormous number of stones and found the crushing operation in children quite feasible I have had very few Someone said that it was a very difficult operation in children That is all wrong It is very easy The bladder in children is small and globular and the stone cannot get away One must be gentle, but the manipulation is easy In the operations I have performed I have been delighted with the ease with which they were done Recurrence has always been an opprobrium of the crushing operation There is danger in any operation of fragments being left I have removed stones in a number of instances after suprapubic operations done for the removal of the prostate When one leaves a suprapubic wound it leaves a granulating surface on the inside, on which *calcareous matter collects and acts as a nucleus for stone* After litholapaxy I always wash my patient out about ten days later, with the idea that somewhere some little fragment may have caught among the folds and not have been removed I remember one case in which I did a number of operations The stone did recur The patient had three or four hundred stones at the first operation, all the way from the size of a good sized bean down to a grain of wheat It was one of my early cases, and I did not wash the patient out afterward, and within less than a year he was back again for a second operation I removed the stones again, they were multiple A fortnight later I washed out 150 minute separate stones from his bladder A week later I washed out fifty I washed him out once a week until I washed him once or twice without getting any I think that subsequent washing out is an important part of the operation

Dr Young spoke of Dr Bigelow's lithotrite I think that he is unaware of the fact that Dr Bigelow devised a fenestrated lithotrite which he occasionally used The fenestrated lithotrite cuts the large stones very easily In operating on children I always use a fenestrated lithotrite After he had broken the stones up Bigelow preferred the solid blade because he could put it down in the bottom of the bladder and crush the stone easily without any danger of thrusting fragments through against the floor of the bladder In my early cases I constantly operated in cases in which the prostates were not removed I have often seen the irritation disappear and the residual urine fall from several ounces to a few drams after removal of the stone One field for stone removal is when they first come into the bladder With my litholapaxy pump I have in my office removed quite a number of renal stones that had been passed from the kidney into the bladder and then had not passed out Of course, behind an enlarged prostate that has any residual urine whatever, a small stone has a very small chance of being passed out, and in these cases the use of the pump will save the patient the subsequent formation of a vesical stone

Dr W E Lower, Cleveland Dr Swan has given statistics for cystotomy far better than anything I have to offer The lithotritists are asking us to do the hard operations and they will do the easy ones The only thing we ask is that we be permitted to do the easy ones as well If the suprapubic cystotomy is properly done and the bladder closed, the patient has no greater discomfort than after the use of the lithotrite It is doubtful if he has as much because of less trauma to the urethra, for there is always a certain amount of trauma to the urethra after the use of the lithotrite and urination is more or less painful.

SEMINAL VESICULOTOMY

ITS PURPOSE AND ACCOMPLISHMENTS *

EUGENE FULLER, M D

NEW YORK

Since the operation of seminal vesiculotomy has been before the profession for a considerable period of time, no attempt will here be made to describe the procedure itself All those desirous of such information are referred to my previous articles[1] My first article was written during the experimental stage of the work, the second, after the procedure had established itself on a firm, practical basis In the second article it will be seen that some of the original experimental technic was abandoned and that improved features were substituted At present, having more than doubled my surgical experience with the operation since the 1909 article was written, my cases then having numbered only 126, I naturally feel that my technic and surgery are more competent than they were three years ago Still in the way of a general description of the operative procedure itself, there is little to add

To any one wishing to perfect himself in this particular, the following suggestions are offered The anatomy should be studied and dissections should be made on the cadaver In accomplishing such dissections the cadaver should be placed in the knee-breast posture, thus simulating conditions pertaining during actual operation Dissection should be made without cutting into the muscular structure of the perineal body, the rectal sphincter muscle or the blood-vessels encircling the anus If this is so done, the bursal space between the rectum and the prostate is entered without injury to a blood-vessel of any size In fact, in the performance of the actual operation the tying of a single blood-vessel is only exceptionally necessary After the bursal space is once entered, the finger-tip suffices, except occasionally when dense pathologic adhesions exist, in accomplishing a separation of the rectal wall from the prostate and seminal vesicles

Aside from an acquaintance with the anatomy of the region traversed by the operation, familiarity with the regional anatomy of the part to be attacked is most essential In common professional parlance, the term "prostate" is seemingly made to include not only the prostatic body proper, but also the seminal vesicles, and should an inflammatory or neoplastic tumefaction occupy a part or the whole of the postprostatic space, such lesion is generally classed also as prostatic, the idea that anything else could exist calling for a differentiation of the diagnosis not being apparently even thought of As the result of a regional dissection, just what constitutes the prostate, the seminal vesicles and the outlying region of the postprostatic space will become apparent

When one considers that the seminal vesicles are cavities for holding fluid, the walls of which, as with the bladder, are made up of muscular structure lined interiorly with mucous membrane, it is not difficult to picture the pathologic conditions so frequently encountered Such conditions in the great majority of instances have to deal with intraseminal vesicular infections of various descriptions, most of which have entered the cavities by the ejaculatory ducts, though in a minority of instances the invasion has been effected by penetrations through the sac walls The distention of the sac cavities due to muscular atony may represent a lesion in connection with which there is no intraseminal vesicular infection Severe grades of infection are not simply intravesicular, but involve the muscular walls of the sacs or (and this is frequent) invade also the outside fibrous lymph-spaces, a periseminal vesiculitis of greater or less degree resulting

As the seminal vesicle discharges its contents by the long narrow ejaculatory duct and only at infrequent intervals, it is readily seen that the organ is not well equipped by Nature to throw off spontaneously an infection, even when confined to the intravesical cavity, and much less so when the process has extended so as also to involve the sac walls and the perivesicular tissues In very extensive infections in which pus collects in the postprostate space outside the seminal vesicles, Nature, if left to herself may discharge the pus into the bladder through the trigonum, into the rectum by perforating the bowel wall, or she may find a way out along the same tract which I employ in reaching the seminal vesicles by operation In such unusual instances the abscess points into the perineum or to one side of the rectum When Nature is left to herself in such cases, the work is not apt to be well done, but requires for its completion much more difficult surgery than would have been necessary had operative interference anticipated natural efforts In most infections the process does not go to periseminal vesicular abscess formation, the bacterial invasion of the tissues causing varying lesser grades of lesions, largely in the nature of round-cell infiltration, serous extravasations and scleroses, all of which serve as lodging-places or nidi for infecting organisms

* Read in the Symposium on Genital Pathology and Surgery in the Section on Genito-Urinary Diseases of the American Medical Association at the Sixty-Third Annual Session held at Atlantic City June 1912

[1] Fuller THE JOURNAL A M A May 4 1901, p 1228 Med Rec New York Oct 30 1909

With this understanding of the pathology of the part, it is easy to comprehend the reason for and the purpose of surgery in this connection The general surgical principle on which the operation of seminal vesiculotomy is based is simply that of drainage Most natural cavities of the body are being constantly opened and drained to free them of inflammatory processes, or of the resultant effects of such processes Consequently, there is no valid reason why surgical drainage should not be applied to these hitherto neglected organs

My reason for laying such emphasis on what probably seems a most elementary and self-evident principle is that there apparently exists a somewhat wide-spread misconception of the operation under consideration Although its name implies that there is no removal of the seminal vesicles, still many seem to think that such is the purpose of the procedure Another very prevalent erroneous conclusion is that incision into the seminal vesicle destroys the organ, and that an individual so operated on is on a par with one who has had the testicles removed The operation is not one of destruction, but of repair Every one knows that incisions for drainage into other cavities, such as the bladder, the renal pelvis and the mastoid, do not destroy functional conditions Their purpose is preservation The same applies to drainage of the seminal vesicles Where disease of the part has threatened or destroyed the sexual function, the operation acts as preserver or restorer Any drainage operation which does not accomplish its purpose is, of course, a failure If this were not the case one surgeon would be as good as another, and operative skill would be no longer an asset of value

In classifying my cases of seminal vesiculotomy, I have found it more satisfactory to group them according to the prominence of the clinical symptoms presented, rather than in accordance with the grades of the pathologic lesions Acting on this idea the four following groupings have been designated (1) urinary, (2) genital, (3) nervous and mental, (4) rheumatic In some cases the symptoms complained of are varied enough to come under all four groups In making the assignment these cases are placed in the group which accords with the most pronounced symptoms In most instances, however, there is little question as to which group should receive the assignment

In the first (urinary) group come most of the acute virulent cases, in which the gonorrheal process in its invasion of the seminal vesicles quickly extends beyond the sac walls and into the surrounding tissues, much postprostatic general tumefaction resulting In these cases the inflammation, after filling the loose periseminal vesicular tissues, works its way forward into the capsule of the prostate, so that when a digital examination per rectum is made a great bulging, rounded mass is felt, which may be extensive enough nearly to fill the space assigned to the rectum Such a tumefaction always markedly disturbs urination and often causes complete retention The tumefaction begins as a round-cell serous exudate, but often goes on to abscess These are the cases commonly mistaken for prostatic abscess The old way of treating them by perineal cystotomy was most unscientific as well as unsatisfactory Routier's method of draining them by way of an incision through the rectal wall has little to recommend it By seminal vesiculotomy, however, relief is prompt and radical Voluntary and free urination is usually reestablished thereby inside of twenty-four hours

Another class of cases in this group represents those in which there is a persistent catarrhal discharge from the seminal vesicles through the ejaculatory ducts, a third represents those in which the symptoms assigned to cystitis are most prominent, periseminal vesicular inflammation having extended into and involved the bladder floor

In the second group the symptoms of sexual impairment predominate, impotency or marked weakness being the usual feature

The third group, in which nervous and mental symptoms are most prominent, is numerically much smaller than it should be, for the simple reason that a smaller percentage of patients with such symptoms have consented to submit to operation Such individuals, because of the nature of their symptoms, are apt to be timid and apprehensive, and consequently are disinclined even to entertain the idea of relief through operation, much less accept such an issue Then, besides, very few neurologists are awake to the fact that surgery has anything to offer these patients in the way of relief, the result is that the great majority of such authorities when appealed to by these patients after the operative issue has been raised throw their influence strongly against the proposition As most neurologists are ready to admit that their methods of treatment, when applied to men suffering from mental or nervous disorders based on a sexual foundation, are very unsatisfactory and in the majority of instances thoroughly inefficient, and as these same authorities do not now hesitate to send their female patients who have similar symptoms to gynecologists for operation, in case their sexual organism is found to require such treatment, it seems most probable that it is only a question of a short time before neurologists will change their present attitude and give their male patients advice in harmony with that accorded the other sex, in other words, they will put the genito-urinary surgeon on a par with the gynecologist

Not everyone, of course who harbors a lesion of the seminal vesicles has nervous or mental symptoms These symptoms are chiefly observed when the sexual disorder has implanted itself on a person whose nervous organism is susceptible or vulnerable In some instances the symptoms are reflex in character, in others, a systemic toxemia, like that which exists in the rheumatic cases, is the accounting cause The mental symptoms complained of are often a confusion of ideas, inability to think clearly or to concentrate the mind, and are especially manifest after sexual disturbances or effort Mental depression, even to the extent of melancholia, is common Marked loss of initiative, trepidation and a high degree of timidity are not infrequently manifest In one instance illustrative of this condition, a man would not walk alone unless he was close to a railing or a fence for fear that he might fall Another physically very strong individual would not cross a ferry, unless his wife held his hand, for fear that he would be blown off These, of course are extreme instances In fact, hysteria in all its varying phases is to be encountered in a clinical study of these cases The nerve symptoms may be multiple and varying, just as in neurasthenia, or they may be fixed and definite In the latter condition, complaint may be of pain in the perineum, the rectum, the back of one or both thighs, the sacrum, the inguinal region, the scrotum, the loin, or elsewhere Such pain, it is often stated, is aggravated by sexual effort or disturbance

The fourth or rheumatic group is most interesting and very important Whereas most of the individuals assigned to the first group and practically all classed under the second and third groups are physically capable, all those of the fourth group are crippled to some extent, while very many of them are bedridden and unable in any degree to care for themselves

My investigations have shown that the ramifications and extent of gonorrheal rheumatism are much greater than is commonly supposed The acute rheumatic complications associated directly with gonorrhea have long been clinically recognized The chronic phase of the complication, however, beginning perhaps a considerable number of years after an infection, has not been recognized, and has been incorrectly diagnosed Tuberculous joint, arthritis deformans, gout, chronic inflammatory rheumatism, progressive muscular atrophy and myelitis of some form are among the diagnoses previously made in cases which I have cured through the performance of seminal vesiculotomy

This drainage operation, by tapping the septic focus, terminates the resulting condition of systemic toxemia, and with such termination there begins a resolution of the crippling lesions, the causative effects While in the acute cases resolution of the rheumatism and its effects following operation is very rapid, in the chronic cases it is naturally by comparison slow It is easy to realize that this must naturally be the case when one considers the atrophic muscular and other changes which are associated with joints and tendons that have for long periods been fixed and immovable In such instances, after the toxemia has disappeared, massage, passive movements and other agencies usually employed in convalescence from fractures or joint injuries of long standing are to be recommended In this connection, however, I would state that I do not begin the employment of these agencies so promptly after operation now as formerly I think it best for the first two or three months following operation to employ no manipulations aside from what the patient may voluntarily undertake If this is done the system is wholly free from all vestige of toxemia before the commencement of postoperative treatment Premature manipulations are associated with painful and inflammatory after-effects

In my earlier experience it was not uncommon to notice, a month or six weeks after operation, some temporary recrudescence of the rheumatic symptoms in cases in which all such symptoms had disappeared promptly following operation This I found to be due to the fact that the outer tract of the wound had been allowed to close before the region of the seminal vesicles had been sufficiently drained To obviate this the drainage-tubes are not now removed for ten days, or until such time as the deeper portion of the wound has thoroughly healed

Just what part the gonococcus itself plays in the causation of gonorrheal rheumatism has not been determined, and the more I study chronic conditions the less I feel inclined to put great responsibility on that organism In many of the chronic cases no gonococci can be demonstrated definitely to exist in the urinary tract or in the material expressed from the seminal vesicles Organisms, apparently streptococci, can, however, be found There is often positive clinical evidence that these individuals are not and have not been contagious in their coitus for a long period It may be that a toxin, a product of the gonococcus, of the streptococcus or of a combination of the two, which is responsible for the rheumatism, is generated in the seminal vesicles This is a laboratory problem yet to be solved In the meantime, I have on many occasions called attention to the fact that the term gonorrheal rheumatism is objectionable and faulty, especially in its application to chronic cases in which very likely the previous existence of a gonorrhea is an event of the forgotten past The term "absorptive or toxic rheumatism" besides being more accurate is also free from criticism

My clinical experience with seminal vesiculotomy now consists of 254 cases Out of this large number there has been no mortality The operative risk must therefore be slight, and with this showing adverse criticism based on the gravity of the procedure should receive no attention The postoperative disturbance, aside from that usually associated with the anesthetic, is slight Retention follows about once in five cases When it does occur the urine rarely has to be drawn more than a time or two Aside from the order to be prepared to use the catheter, if required, the chief direction is to give castor oil twenty-four hours after operation, and from that time on to see that the bowels are properly moved every day

My second article ended with the report of my one hundred and twenty-sixth case In thirty-five of these 126 cases the operation was undertaken for the relief of gonorrheal rheumatism In the 128 patients operated on since that report, rheumatism figured as the cause for operation in eighty-nine cases The reason for this marked increase in the rheumatic ratio in the second series can be accounted for as follows

The first time the operation was employed to relieve rheumatism was in connection with my thirty-eighth case, as before that I was not awake to the fact that the operation could be so employed Since then, the operation with a wider experience has been found applicable not only to the acute rheumatic cases, the only ones first tried, but also to the chronic cases As such affections cripple and physically incapacitate a greater percentage than do the other groups of symptoms, it is natural that the rheumatics should outnumber the others in seeking operation

Of the remaining thirty-nine cases, eighteen belonged to the first or urinary, fourteen to the second or genital, and seven to the third or nervous and mental group

Of the eighty-nine rheumatic patients there was not one who was not relieved in a most radical manner and who was not satisfied with the operative result Eighty per cent of the patients were well and free from all symptoms when they passed from observation a month or six weeks after operation All were instructed to report should any future disturbances arise nothing official has been heard from them The remaining 20 per cent, mostly representative of chronic conditions, I have not been able to keep under observation until a complete resolution of the rheumatism had taken place All of them had been so much improved that retention in hospital was no longer required M [illegible] had insisted on being discha[illegible] they [illegible] look after themselves, while two or three had been discharged for violation of disciplinary rules. I hear from these last patients occasionally, and all such reports are either cures or progressive improvements.

One man, operated on three years ago, after having been bedridden or about on crutches for seven years, has for the last two years been an orderly at the City Hospital, in perfect physical condition. A very few patients, mostly those with flat feet, were turned over to the orthopedic department after thoroughly convalescent. Several of the clinical patients, owing to their pain, had become addicted to the use of opium. In every such instance all opium was stopped at the time of operation. In these cases convalescence was, as a rule, somewhat slower, owing to the breaking of the drug habit.

Two of the eighteen urinary patients proved to have an underlying tuberculous condition, which prevented an operative cure. My rule is not to subject tuberculous seminal vesicles to this operation, and care is taken to avoid operation in such cases. One urinary patient, whose case was representative of periseminal vesicular abscess had to leave the hospital to resume work before he had recovered; the result was a relapse. This patient, when last seen, was much better. Three other patients sought their discharge from hospital before they had time to become cured. The remaining twelve patients passed from observation cured.

In nine of the fourteen genital cases the patients were satisfied when they passed from my observation. I have no reason to suppose that the results in the remaining five cases were not satisfactory; I have heard nothing to the contrary. It takes from three to six months to get the end-result in these genital cases, and before that time some of the patients disappear.

Operative results in the seven mental and nervous cases were all satisfactory, though two of the patients passed from observation somewhat prematurely.

These results, taken as a whole, are most satisfactory. Still, it is not expected that seminal vesiculotomy will ever become an operation to be performed by everyone professing efficiency in general surgery, and it is to be hoped that those who have not previously made an attempt to fit themselves for its technic will not try it. This may also be said with regard to many operations. Few, if any, attempt iridectomy, for instance, without preliminary training.

My reason for making these precautionary remarks is that the operation of seminal vesiculotomy is done under the guidance of the sense of touch rather than that of sight. Some surgeons are not trained to put any dependence on their touch, but must see everything before using a knife. Genito-urinary experts have to be trained in the touch. Certain of their operations, as litholapaxy, depend entirely on that sense. Anyone who has skill in surgical technic and also a finger trained in the rectal touch should have no trouble in becoming expert in seminal vesiculotomy; he will then be able to relieve a large class of patients who have hitherto been, as it were, surgical derelicts.

The Open Air Bedroom.—The ordinary bedroom for most persons is well enough. Its only trouble is that it does not admit enough air. Let us not drive out the occupant on this account, but reform the bedroom. It can be done with astonishing cheapness and ease, simply by putting in many windows.—E. Cummings in *Jour. Outdoor Life*.

DEATH AND BLINDNESS FROM METHYL OR WOOD-ALCOHOL POISONING

WITH MEANS OF PREVENTION

CASEY A. WOOD, M.D.
CHICAGO

Surely the man who wishes well of his country should be interested in preventable diseases. Inevitable evils one bears with greater or less equanimity, but those forms of ill health that are plainly avoidable should be ruthlessly traced to their sources and eradicated.

Hygienic crusades are all the more likely to be successful in America since we have recently experienced a great moral uprising against those deadly agents, adulterated foods and quack medicines. It is no longer respectable or safe for wholesale or retail purveyors of food and drink to substitute for them any poison their fancy dictates. The demand for articles that are at least what they claim or seem to be has at last become so loud and persistent that no government can afford to ignore it. Now that the sale of spoiled, noxious or adulterated food is beginning to be regarded as a low form of thievery not uncommonly tinged with manslaughter, the common people are likely to come into their own.

It is for the purpose of bringing to the attention of our citizens the dangers that lurk in the use of certain forms of methyl or wood alcohol that this paper has been prepared.

Thirty years ago poisoning from wood alcohol, methyl alcohol, wood spirit, methylated spirits, etc., was almost unknown. The disgusting odor and vile taste of this product of the destructive distillation of vegetable fiber were so repugnant to the palate and nasal organs that one would about as quickly drink crude petroleum. About 1890, however, a comparatively cheap method of "deodorizing" this ill-smelling and vile-tasting liquid was discovered, and under various names, such as "Columbian Spirits" (Fig. 1), "Purified Wood Alcohol," "Colonial Spirits," "Standard Wood Spirits" (on the Canadian market, Fig. 2), "Cologne Spirits," "Union Spirits," "Eagle Spirits," "Green Wood Spirits," etc., this violent poison was put on sale. It was widely and shrewdly advertised and all sorts of virtues were claimed for it, the chief being that it was a cheap and comparatively harmless substitute for ordinary ethyl or grain alcohol. Not only could it be used instead of grain alcohol in making varnishes, liniments, tinctures, hair-dyes, etc., and as a fuel in lamps and stoves, but also at first its poisonous character was denied *in toto*. This last claim led to its use not only for these purposes but also in the manufacture of Jamaica ginger, essence of lemon, liniments, alcoholic extracts, cheap whisky and proprietary "remedies;" generally speaking, in those instances in which the manufacturer regarded his business as a means of getting money "honestly" when there was no danger of being found out.

Soon, however, stories of sudden death as well as of total and incurable blindness following the use of this horrible poison began to appear, not only in medical journals but in the public press. It was not until a wholesale drug firm in Baltimore had been mulcted in heavy damages for attempting to "turn an honest penny" by the use of "deodorized" wood spirit as a substitute for the four-times-as-expensive grain alcohol in the manufacture of Jamaica ginger, that the trade began "to sit up and take notice."

Later, examples of wholesale poisoning began to be reported. Parties of all classes of people — workmen, picnickers, bar-room habitués, Indians, etc — indulging in cheap whisky and its substitutes died or became blind Still later, it was found that unfortunate painters, especially shellackers of beer-vats, working in confined and unventilated places, were stricken with blindness, and on investigation it was conclusively proved that the befouled, rebreathed and methylated atmosphere was responsible for the result Cheap varnish made with "Columbian Spirits" costing about 50 cents a gallon (grain alcohol is about $2 40 a gallon), had done its deadly work

In the years 1903-1904 the late Dr Frank Buller of Montreal and myself set about collecting the histories of cases of poisoning to that date Doubtless many instances of wood-alcohol poisoning escaped this inquiry, but we found and reported[1] 275 instances of death or blindness (sometimes both) directly traceable to drinking, or inhaling the fumes of "Columbian Spirits" or some other form of "deodorized" wood alcohol At that time we drew the following conclusions

1 Methyl, or wood alcohol, in any of its forms, and all methylated preparations as well, are dangerous poisons, menacing both life and eyesight

2 It is used as an adulterant of, and substitute for, grain alcohol in cheap whisky and other alcoholic beverages, not to mention Jamaica ginger, lemon extract and many other essences and flavoring fluids

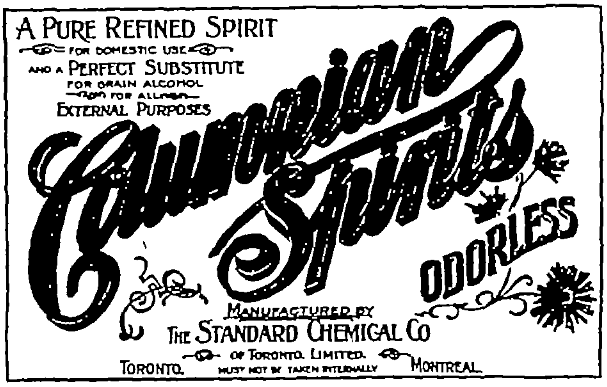

Fig 1 —A label used on Columnian [Columbian] Spirits Note how obscure is the warning not to take this poison internally

3 Methyl alcohol is largely used in the preparation of many proprietary and patent medicines, witch hazel, domestic liniments, as well as bay rum, cologne water, Florida water and other perfumes

4 The injury to the eyesight consists chiefly of a destructive inflammation of the optic nerve fibers or retinal elements (or both), followed by their atrophy

5 The symptoms of acute poisoning are gastro intestinal disturbances, more or less severe, accompanied by abdominal pain, general weakness, nausea, vomiting, vertigo, headache, dilated pupils and blindness If recovery does not occur, there is marked depression of the heart's action, sighing respiration, cold sweats, delirium, unconsciousness, coma and death

6 The blindness is bilateral and may set in a few hours after the contact with the poison, or it may be delayed for several days It is generally complete, with a subsequent improvement, and, finally, a relapse into permanent blindness

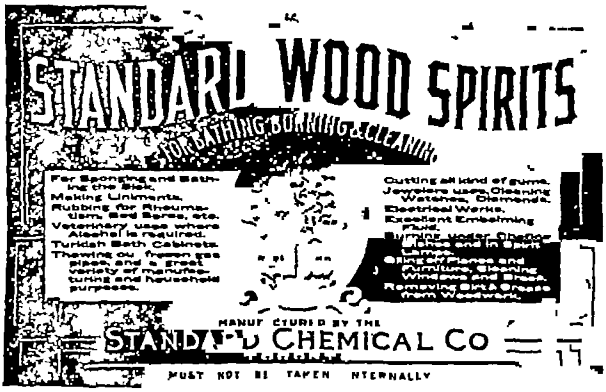
7 The diagnosis can hardly be mistaken Methyl alcohol poisoning presents a picture unlike that of any other intoxication Acute abdominal distress, followed by blindness, should always awake suspicion of methyl alcohol poisoning

8 The prevention of poisoning by this insidious drug can only be brought about by prohibiting [or rendering unprofitable] the sale of "deodorized" wood alcohol in all its forms The number of deaths may, meantime be limited by putting all methylated preparations on the list of poisons and prosecuting all persons adulterating foods and drinks with it Labeling it with the notice, 'This fluid, taken internally, is likely to *produce blindness" will certainly have a deterrent effect*

9 Methyl alcohol intoxication is an example of idiosyncrasy As in the case of several other poisons, some persons are largely immune so far as permanent damage to the organism is concerned If ten persons drink, say, 4 ounces of Columbian spirits within three hours all will have marked abdominal distress and probably four will die two of them becoming blind before death Six will eventually recover, of whom two will be permanently blind With still larger doses, the proportion of death and blindness will be greater

10 Poisoning by inhalation of the fumes of methyl alcohol generally occurs when the exhalations are mixed with rebreathed air, as in varnishing the interior of beer vats, closets or small rooms, etc It is also highly probable that in susceptible subjects repeated or even single methylated "alcohol rubs" may produce poisonous symptoms, through absorption of the spirit by the skin

11 Chronic (or partial) poisoning from methyl alcohol (in the shape of "nips" of methylated Jamaica ginger, bay rum punch made with Columbian spirits, etc.) is the most insidious and probably not an uncommon form of intoxication Its symptoms are not so pronounced or so easy of recognition as in the acute form, but the eyes, digestive apparatus and nervous system undoubtedly suffer



STANDARD WOOD SPIRITS
FOR BATHING BURNING & CLEANING
For Sponging and Bathing the Sick.
Making Liniments.
Rubbing for Rheumatism, Bed Sores, etc.
Veterinary uses where Alcohol is required.
Turkish Bath Cabinets.
Thawing out frozen gas pipes, and a great variety of manufacturing and household purposes.
Cutting all kind of gums.
Jewelers uses, Cleaning Watches, Diamonds.
Electrical Works.
Excellent Embalming Fluid.
MANUFACTURED BY THE
STANDARD CHEMICAL CO
MUST NOT BE TAKEN INTERNALLY

Fig 2 —Another deodorized wood alcohol poison It is recommended for bathing rubbing and sponging the sick for making liniments also for use in chafing dishes and in spirit lamps See how little is said about its poisonous qualities

12 The use of ethyl or grain alcohol in the arts, as in the manufacture of varnishes, as a burning fluid, for "stiffening" hats, lacquering brass, etc, is without danger to life or eyesight If a small percentage of naphthalin, for example, were added to it, the fluid would be undrinkable A combination of ethylic alcohol with 10 per cent of wood spirit would answer the same purpose Such a mixture is the 'methylated spirits" of Great Britain, where not a single case of acute poisoning or blindness from methyl alcohol is recorded, in spite of the extensive use of methylated preparations in the British Isles

13 The treatment of *methyl alcohol intoxication* consists chiefly in getting rid of the poison from the stomach and intestines by means of the stomach pump and rectal injections, stimulants, especially *ethyl alcohol*, strychnin and coffee, heat to the body and extremities

14 The treatment of the blindness is unsatisfactory

however, that once absorbed, from either the stomach or the lungs, into the blood, it is not so easily eliminated or burned up as is ethyl alcohol, as which it masquerades in commerce.

This peculiarity of methyl alcohol is of considerable importance and interest because becoming cumulative in the system, small and frequent doses of the poison in the form of quack medicines, hair-tonics, cheap whisky, or essences, rubbing the body after Turkish and other baths, burning in "alcohol" lamps, varnishing pianos, beer-vats, small rooms, etc., insidious and often unsuspected but serious damage to the digestion, sight and nervous system may be induced.

After Columbian Spirits and similar "deodorized" poisons had been in the export market for a few years, we began to hear from other countries where, as in America, until this development of the wood-alcohol industry, poisoning from methylated spirits had been entirely unknown. About the time (the end of 1904) that twenty persons were poisoned in Kentucky, an equal number of wood-alcohol victims were, within twenty-four hours, killed and blinded in Dorpat, Russia. The Russian physicians were very much interested in and excited by this destruction, but our cases did not disturb us greatly; *we* had lived too long with the wood-alcohol "trust" for that. It only seemed to us that another infant industry had grown up and had reached a foreign shore. Later on, it will be seen how Columbian Spirits, or a replica of it, has recently invaded another country hitherto free from it.

As a result of these "accidents" a wide-spread agitation against the unrestrained sale of this poison was begun and kept up in both the medical and the lay press of the United States. As a further contribution[2] to this campaign I reported several examples of wood alcohol intoxication which had not been published up to that time, and closed with the following observations on its prevention:

> My colleague, Dr. Frank Buller, has suggested that every package, wholesale and retail, of "deodorized" wood alcohol, bear the warning, "This fluid, taken internally, is likely to produce blindness." Such a legend might be even more effective than the word "Poison" and the familiar picture of the skull and cross bones, chiefly because to most people the fear of blindness is more impressive than that of possible death. No doubt this precaution would limit the dangers of serious poisoning from methylated preparations, but it is very doubtful whether it will ever be entirely effective. Whenever a government permits the manufacture of "deodorized" wood alcohol (as in the case of Columbian Spirits in the United States and of Standard Wood Spirits in Canada) the only effective, natural safeguards (the offensive odor and taste) against ingestion of the poison are removed and the annual sacrifice to death and blindness will certainly continue. Either the manufacture and sale of "deodorized" or "purified" wood alcohol should be absolutely prohibited or, as in Germany and Great Britain, an untaxed (grain) ethyl alcohol, or one rendered undrinkable by the addition of mineral oil, wood spirit, naphthalin or some other nauseous compound should be allowed for use in the arts in the place of Columbian Spirits and similar dangerous preparations.
>
> The fact that the consumption of millions of gallons of cheap alcohol in other countries has been going on for years without fatal consequences, while in America we have had hundreds of deaths and cases of blindness from the employment of an agent that possesses no advantages over the British Methylated Spirits, or the German *Brennspiritus*, is surely an unanswerable argument in favor of this proposal.

After a time and partly in consequence of these investigations, but more directly as the result of discussions in the newspapers and of resolutions passed by the Section on Ophthalmology and House of Delegates of the American Medical Association, several bills were finally introduced into Congress providing for a cheap, commercial, grain alcohol which would render unnecessary and drive out of the market dangerous forms of "deodorized" wood spirit. The success of the movement was largely due to a committee of manufacturers formed to assist in securing cheaper alcohol for industrial purposes, headed by Mr. Henry Dalley of New York. After considerable discussion of the project by Congressional committees and the hearing of much evidence, especially that furnished by a number of workmen blinded by using Columbian Spirits in their ordinary occupations, the bill introduced by the Hon. W. Payne was passed by Congress, June 7, 1906. We now have as a result of this legislation what is known as "denatured alcohol," a harmless grain or ethyl alcohol, rendered unfit for drinking purposes by an admixture of various ingredients that do not destroy its value for domestic consumption and for the purposes of commerce.

Denatured alcohol is as cheap as or cheaper than Columbian Spirits or any other kind of "deodorized" wood alcohol and can be bought at drug-stores wherever the "deodorized" poisons are or have been on sale. Not only is there no longer the least excuse for the sale of "deodorized" wood spirits but, in my judgment, its manufacture should be prohibited by law. Why? Because it serves no purpose that "denatured" alcohol will not serve and because its existence is everywhere and at all times a menace to the public health. It looks, smells and tastes so much like grain alcohol that its very existence must ever be a challenge to life and sight.

Moreover, in spite of all the agitation in the press and the education of the public by other means an immense amount of ignorance exists and, in the nature of things, will continue to exist regarding the poisonous character and legal status of this deadly agent. For example, in commenting on a suit for damages brought by the widow of a poor varnisher, who had died from inhaling the poisonous methylated air of a beer-vat in which he had been working, a certain brewer alleged that the denatured alcohol used as a solvent for shellac "spoiled the beer" and was not as good as the "deodorized" product—which improved it, I have no doubt. Instead of being merely mulcted in heavy damages, as was the defendant in the case referred to, it is to be hoped that future criminals of this class may find their way to the penitentiary.

As another example of the ignorance still prevailing among those that ought to be better informed, let me refer to the first (or almost the first) cases of wood alcohol poisoning known in Germany. In that country, as in England, there has, for the past thirty or forty years, existed a cheap, tax-free commercial alcohol and, in consequence, there never has been room for any form of "deodorized" poison. For the same reason, also, there is not a single authentic report of poisoning in Great Britain. Whether a few barrels of American "deodorized" alcohol found sale in Prussia or whether the product was a local one seems difficult to decide, but shortly after celebrating the Christmas (1911) holiday "with the aid of wine," 161 inmates of a municipal shelter in Berlin became violently ill and seventy-one of them died. The German physicians knew little or nothing about our wide and varied experiences with methyl alcohol poisoning, and attributed the illness to decomsed meat and other causes until an official in the police partment found that the *Schnapps* which had formed portion of the Christmas celebration was largely arged with methyl alcohol Later, the suspected meat d sausage were found to be harmless, while a post-ortem examination disclosed the presence of methyl cohol in the stomachs of the victims

[2] Wood, C. A.: Poisoning by Wood or Methyl Alcohol and Its Preparations as a Cause of Death and Blindness, New York Med. Jour., Jan. 7, 1905.

Another example — and many more might be given — the ignorance of those who ought to know better is en in the death (March, 1911) of one workman (J M) d the total blindness of his fellow workman L, due inhalation of wood alcohol fumes while varnishing e interior of a beer-vat in a Buffalo brewery For a ort time these "accidents" were attributed by certain ficials to the fumes of a charcoal stove!

That cases of death and blindness from "deodorized" ood alcohol are still occurring in America, and that olumbian Spirits and similar poisons are responsible r them and are still extensively sold can easily be monstrated, but I will report only a few more or less cent examples typical of serious intoxication

Commenting on the death of four men and the blind-ss of one man in Whitestown, Indiana, about Aug 16, 11, Dr P B Little of that town writes me

> It seems that these men purchased and made a mixture of gallon of wood alcohol and 3 gallons of grain alcohol and all nk freely of it The symptoms that followed soon after ere chiefly headache, nausea, vomiting, extreme weakness, mmy sweats, weak pulse, blindness, dilated pupils, cyanosis, ghing respiration, convulsions and death The blindness came six to eight hours before death The survivor of this bauch was the first to fall sick and the first to become blind

Gustav K., 21 years old, went to work for a contracting rnisher in New York the week before Thanksgiving, 11 He worked Thursday, Friday and Saturday, ovember 23, 24 and 25 He was then laid off until onday, December 4

An older brother of Gustav was also hired, beginning Monday Two other men and these two brothers ere the only men working on the job They had to awl through a small opening into the vats, which were 2 or 15 feet high, closed, dark and airless, except for ight ventilation through the small openings The rmer employer of the two brothers had used a small achine run by a dynamo for blowing out bad and sendg good air into the vats Such an engine costs about 65 and, in the opinion of Gustav K , he became blind ecause the employer would not spend anything on ventitors The victim stated that his employer obtained e contract by underbidding the man for whom the rothers had formerly worked

Gustav K worked Monday and Tuesday, December 4 nd 5 On Monday, after coming out of the vat he felt izzy On Tuesday, after arriving home, his mother emarked that he walked as if he were intoxicated ednesday morning he had a terrible sweat, vomited, nd had a rash on the face and body He tried to go to ork but had to come back before getting on the car e could not see very well then A physician was consulted twice but because he could not afford to pay the ee, the patient went to the Ophthalmic and Aural Institute on Tuesday, the 12th When he entered the hospital e could not see at all On Friday, the 15th, he could ee just enough to get about the room in the hospital

The older son, who had been working at the same me as his brother, worked through Wednesday, the 6th one day longer), and then showed some of the symptoms f poisoning, reeling headache, etc , but no more serious ffects The mother said, when seen on Thursday, that the son was then intending to return and continue the work, because he could not find work anywhere else

The two men who had worked with the brothers continued through Wednesday Both were poisoned, one died on Thursday and the other on Saturday From a child of one victim the following note was received

> Your letter to hand and wish to state that two or three days before my father's death he came home as though he was intoxicated He vomited all day Thursday, which was one day before his death He had chills and fever very often He must have been losing his eyesight before his death because my sister told me that although she had all the gas jets lit yet he begged her to light them, he also complained of his eyes burning like fire I am not living at home and did not see my father when he came home on Thursday night feeling worse than ever but I was there when he died, unconscious, Friday morning at half past five

I am indebted to Miss Louise Schofield, assistant secretary of the Committee on Prevention of Blindness of the New York Association for the Blind, for the pathetic report of the New York cases I may add that this committee, with Miss Louise Lee Schuyler as chairman and Miss Carolyn C Van Blarcom as secretary, is heartily and constantly working in conjunction with Dr F Park Lewis of Buffalo, N Y, chairman of the committee on Prevention of Blindness of the American Medical Association, to further the aims of their respective organizations

At the last meeting of the American Medical Association (Atlantic City, June 3, 1912) Dr Lewis reported that the extent of blindness due to wood alcohol is everywhere in evidence and the suggestion was made that every retail liquor-dealer in the country be sent a pamphlet acquainting him with the fact that in many cases even a teaspoonful of the drug will cause a man or woman to become sightless Efforts will also be made to make it illegal to sell wood alcohol except under the name of "wood poison "

Columbian Spirits and other dangerous forms of "deodorized" or "purified" makes of the wood alcohol poison are still sold in the drug-stores of the United States and Canada To those who think that poisonous imitations of common or grain alcohol are no longer a menace to the health, I would say that inquiry at the nearest large drug-shops and at most general country stores will throw some light on the subject

During the month of August, 1912, I purchased a small quantity of Columbian Spirits at ten of the principal drug-stores in Chicago, at the same time inquiring the price of "denatured' alcohol The results of this inquiry are set forth in the accompanying report Among other items of information it will be noticed that four drug-stores placed no "Caution" or "Poison' label on the bottle The others complied with the law on poisons to the extent of a precautionary notice or label but there was no registration of the name of the purchaser, as I believe there should be in the case of such a violent poison as "deodorized" wood alcohol Note also, that the price of "denatured" alcohol is generally quoted lower than Columbian Spirits What excuse, then, except ignorance, is there to justify the use of the latter?

No 1 Columbian Spirits, half pint, 20 cents Poison label on bottle This drug store does not carry denatured alcohol

No 2 Columbian Spirits 25 cents a pint Poison label on bottle Denatured alcohol 25 cents a quart

No 3 Columbian Spirits, 25 cents a pint No poison or caution label of any kind on bottle Denatured alcohol 25 cents a quart

No 4 Columbian Spirits, 20 cents a pint Poison label on bottle Denatured alcohol 25 cents a quart

No 5 Columbian Spirits 30 cents a pint Poison label on bottle Denatured alcohol 30 cents a quart

No 6 This drug store carried no Columbian Spirits Wood alcohol 20 cents a pint They inquired for what purpose the wood alcohol was to be used Poison label on bottle Denatured alcohol 20 cents a pint

No 7 Columbian Spirits, 25 cents a pint No poison or caution label on bottle Denatured alcohol 25 cents a quart

No 8 Columbian Spirits, 25 cents a pint Poison label on bottle Denatured alcohol 25 cents a quart

No 9 Columbian Spirits, 25 cents a pint "For external use" printed on label Denatured alcohol 75 cents a gallon

No 10 Columbian Spirits, 20 cents a pint No poison or caution label on bottle Denatured alcohol 25 cents a quart

Although ordinary "unpurified" wood alcohol or wood spirit is also a poison, its vile taste and smell are sufficient guarantees that nobody will either drink or inhale it to any deleterious extent For burning lamps, for cleaning brass and woodwork, etc, common wood alcohol is all right if one does not object to the odor and is unwilling to pay a few cents more for denatured alcohol It is quite otherwise with Columbian Spirits, Cologne Spirits, Standard Wood Spirits and all the other forms of "deodorized" methyl alcohol It is to the "pure, refined spirit for domestic use," the "perfect substitute for grain alcohol" (as the labels read) that one objects That subtle and often unsuspected poison has not only been directly responsible for the fate of hundreds of blind people but bids fair, under present conditions of sale and manufacture, to kill and blind additional hundreds

Although for half a century Great Britain, Germany and other European countries have yearly consumed millions of gallons of industrial grain alcohol, "denatured" by processes similar to ours, yet not a single instance of death or blindness has been reported from its occasional ingestion This satisfactory result is due not only to dilution of the poison, whose toxic properties are much modified by the large admixture of grain alcohol, but to the fact that it is almost impossible for even the most insensitive lungs and the most hardened stomach to receive and retain enough methyl alcohol in the various denatured products to induce serious consequences We are consequently justified in asserting that "denatured" alcohol is practically a harmless mixture and may be used for all the purposes, even as a beverage, for those who like it, without producing methyl alcohol blindness or death

HOW WE MAY MOST EFFECTIVELY PREVENT WOOD-ALCOHOL POISONING

Whatever occupation, professional or lay, you pursue, your aid in drawing attention to the hidden evils of "deodorized" methyl alcohol and all its preparations will be most valuable if you not only avoid the use of the poison yourself but discourage its employment by your friends, acquaintances and associates Tell them that we have an equally cheap, commercial substitute — a harmless "denatured" grain alcohol — that answers every purpose, domestic and other, of wood alcohol Also ask your druggist why he sells the poisonous article when there is a government-authorized grain alcohol that does not expose his customers to the dangers of Columbian Spirits and other forms of wood or methyl alcohol By thus discouraging the sale and use of "deodorized" and other forms of wood spirit you aid in that campaign of education which is the most effective agent in protecting the public body from one of the most insidious of our drug and food poisons

7 West Madison Street.

A PLEA FOR LONGER INTERVALS IN MILK-FEEDING *

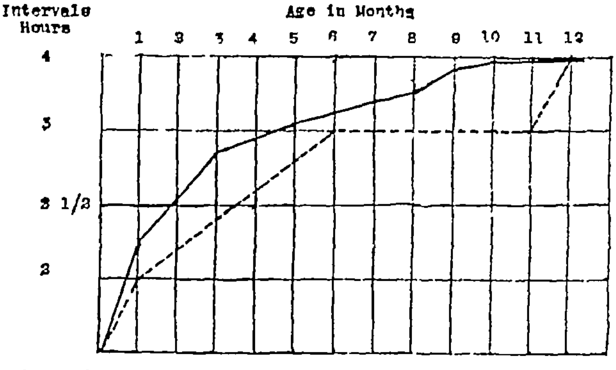
JULIUS H COMROE, A.M, MD
Physician to the York Hospital, etc.
YORK, PA

A careful and thorough review of standard medical text-books and current literature dealing with the principles of infant-feeding reveals the astonishing fact that comparatively little attention is devoted to one of the most important and vital aspects of this subject the intervals of milk-feeding during the first year The many thousands of general practitioners who necessarily must be guided primarily by these written expressions of experienced teachers have fallen victims to the same evil results that empiricism has produced in many other branches of medicine The conventional two-hour intervals during the first month, gradually increased to two and one-half hours until the third or fourth month and thereafter to three hours, have been copied from text-book to text-book and dismissed with little or no further consideration or comment

TABULATED REPLIES FROM 117 PEDIATRICIANS IN THE UNITED STATES AND CANADA

Age in Months	Intervals 2 Hour	 2½ Hour	 3 Hour	 4 Hour
1	66	17	33	1
2	27	40	39	2
3	12	40	63	2
4	8	9	99	6
5		3	105	9
6		8	78	36
7			72	45
8			57	60
9			42	75
10			30	87
11			30	87
12			30	87

Are longer intervals satisfactory? Yes 102 no 15



Composite chart showing natural trend for longer intervals. The line of dashes indicates the intervals computed from average text book teachings the solid line indicates the average intervals of 117 pediatricians in the United States and Canada

In order to determine whether or not the actual practices of the pioneers in infant-feeding coincided with the preponderance of didactic and written teachings of to-day, 135 circular letters were addressed to leading pediatricians throughout the United States and Canada, preference being given to teachers in medical schools and to authors of recognized text-books dealing with this topic A tabulation of the 117 replies received and the construction of a composite chart from these brought to light some interesting and valuable statistics, and demon-

---

* Read in the Section on Diseases of Children of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912.

strated beyond doubt that the trend toward longer feeding intervals is becoming almost universal During the first month of infancy only sixty-six, or 56 per cent, employed the two-hour intervals, seventeen, or 15 per cent, the two-and-one-half-hour intervals, thirty-three, or 28 per cent, the three-hour intervals, and one, Dr J P Sedgwick, or less than 1 per cent, the four hour intervals From the second to the fifth months, the three-hour intervals were employed with increasing rapidity, and thereafter the four-hour intervals were favored, especially on and after the sixth month These facts alone should at once prove the comparative uselessness and empiricism of modern text-book and possibly medical school teachings, and also emphasize the urgent necessity for some hasty revisions and additions along these lines

That each child is a law unto itself and that the intervals of feeding must be largely an individual and not a mechanical routine matter, no one will even question It is likewise well known that infants vary greatly in gastric capacity, in rapidity of digestion, in satisfaction as to the amount of feeding, and in susceptibility as to quality of food, etc, so that there can be no set rule regarding their feeding relative to time, quantity or quality of feedings, and each child must necessarily be fed as a unit rather than according to any inelastic fixed scheme or system It is also agreed that delicate and premature children, and babies that have been improperly fed or who suffer from malnutrition as a result of intestinal disorders, cannot be included in any general plan of feeding But it does seem quite apparent that overfeeding is one of the most common causes of nutritional disturbances in early infancy, and there is little doubt that this has been engendered oftentimes by the indiscriminate introduction of too many feedings in the twenty-four hours

TIME REQUIRED FOR EMPTYING STOMACH

At this juncture it is of the utmost importance to learn the period of time that is usually required for the stomach completely to empty its contents into the pylorus Leo made careful observations, with the aid of the stomach-tube, in thirty "normal" infants whose ages ranged from 2 hours to 12 months, and also in 104 babies who were suffering from various forms of gastro-intestinal diseases In the breast-fed he found the stomach empty in about one and one-half to two hours, and during the first week of life, in one hour In the artificially fed infants, and especially in the older children of the series, a portion of the food was found to remain in the stomach for a somewhat longer period

Pipping made similar examinations in twenty-nine normal infants under 3 months of age, and learned that the stomach emptied itself in about two hours

Czerny states that cow's milk takes up more hydrocholoric acid than does human milk, and in order to retain the bactericidal property of the gastric juice, which is due to the free hydrochloric acid, he urges the advisability of longer intervals between feedings, especially so when cow's milk is employed He found that whereas the stomach of a young infant is empty after an interval of two hours, when several feedings are given in rapid succession, considerable remains of the last meal may be found even after three or four hours This fact, in his opinion, also speaks in favor of lengthening the feeding intervals

Pfannenstill first employed the phenyl salicylate (salol) test for the determination of the time required for food to pass into the intestinal tract By this method phenyl salicylate was administered, and the urine, which was collected by means of a catheter kept in the bladder during the entire period of examination, was subjected to chemical analysis every five minutes In sixty health children the ferric chlorid reaction appeared in the urine forty to sixty minutes after the ingestion of food mixed with phenyl salicylate

Employing the same method, von Hecker found that the time of appearance of the ferric chlorid reaction varied considerably in direct proportion to the age of the child In my opinion this test is not a most reliable one as the elimination of phenyl salicylate, as computed by the urinary reaction, does not necessarily prove the complete emptying of the stomach contents

Meyer, who discarded milk entirely and employed barley-water, sterilized water or normal salt solution, on the ground that with these mediums organic acids do not appear and that the presence of hydrochloric acid in its free and combined state is thus more readily determined, found that in seventeen artificially fed children the stomach was empty in one to one and one-third hours These figures would naturally be comparatively useless in estimating the time required for milk to pass into the pylorus

Heiman made careful studies in a series of thirty-three cases including twenty new-born nursing infants from 3 to 7 days old, and thirteen artificially fed children ranging from 3 weeks to 7 months In the former, practically the same quantity of gastric contents was obtained at the end of one hour as at the termination of one-half hour, and after two to two and one-half hours, 0 5 to 3 c c could still be recovered with the stomach-tube In the bottle-fed babies the stomach was found empty in two hours in four out of thirteen cases, in five cases, at the end of three hours, and in the remainder, in about four hours

According to the investigations conducted by Tobler, and Bogen and Heubner, milk passes into the pylorus in the case of breast-fed infants in about two hours, and in those taking cow's milk, in about three hours Tobler, by employing variously colored milks, has further conclusively shown that each subsequent feeding forms a sort of layer about the earlier one, and that the food first ingested may thus be kept in the stomach more or less indefinitely if the feedings are given at too frequent intervals This constantly recurring contamination and overburdening of the stomach may result in fermentation, and in time in gastric dilatation with a loss of tone of the muscular coats of the stomach, and even in atrophy In their investigations with the Roentgen rays, by which as small a quantity as 5 c c could be determined without the aid of bismuth, Tobler and Bogen further verified the above results and found that the presence of fat considerably delays the emptying of the stomach (probably due to the inhibitory action of the fat on the secretory glands of the stomach and the long-continued closure of the pylorus) and that carbohydrates often act conversely

Mosenthal also found that it required about two hours for milk to pass through the pylorus in the case of breast-fed children and three hours in those taking cow s milk, and the same results were confirmed by the observations of T Wood Clarke, E Cautley, Miller and others

Chapin made careful observations in twenty-one babies suffering from various forms of malnutrition to determine the gastric motility Their ages ranged from 2 weeks to 1 year (one 2 weeks one 3 weeks, one six weeks, one 2 months six 3 months four 4 months, two 5 months, one 6 months one 7 months, three 1 year) Of nineteen patients examined, at the end of three hours only six had approximately empty stomachs, and these six, with one exception, were holding their own In the remaining thirteen cases there was a considerable residual amount of food still remaining in the stomach after three hours In the latter cases a positive Fehling's reaction was present in addition to curds and whey, either singly or together In five of seven patients examined at the end of three and one-half or four hours the stomachs were entirely empty, but in the remaining two cases of this series many curds were present at the end of four and one-half hours in one case, and a few small curds in the other In only two of seventeen patients examined at the end of two or two and one-half hours were the stomachs found empty, and in thirteen, large tough curds, or many smaller ones and whey were invariably present On these results Chapin concludes that in a large majority of cases the feeble infant with digestive disturbances has been fed at too frequent intervals At best, the musculature of the stomach and intestines is not highly developed during the first month of life, and less so in feeble infants Too often a second feeding is administered before the previous meal has entirely passed into the pylorus, with the expected result that each successive feeding has become contaminated The process of butyric acid fermentation has thereby been set up and kept in operation until, at last, a condition analogous to that of myasthenia gastrica is produced

TOO FREQUENT INFANT-FEEDING

With such an abundance of evidence obtained from the most careful and painstaking observations of eminent pediatricians, even the most skeptical will not deny that the intervals of feeding as usually taught are not compatible with physiologic findings It has been conclusively shown that the stomach in the healthy nursing babe is rarely empty in less than two hours, and that in the artificially fed, the time required is usually an hour longer According to Chapin and others these periods are further prolonged in the case of children suffering from various forms of malnutrition And it is reasonable to suppose that as the age increases the time required for emptying the stomach will naturally be lengthened owing to the fact that (1) the quantity and quality of food are increased and (2) as the stomach takes on greater powers of digesting its contents, its secretions act on the milk, forming compounds which remain longer in the viscus Time should therefore be permitted for the stomach to empty itself almost, if not completely, before another feeding is given

It is interesting to note that it is the almost unanimous finding of observers that in the artificially fed babe a decidedly longer time is required for complete emptying of the stomach Of the ninety-three replies to the query "Do you recommend as a rule longer intervals in the artificially fed (as compared with breast-fed) infants?" forty-eight answered in the affirmative and forty-five in the negative According to Engel, breast-milk is digested for the most part in the intestines, and to a lesser extent in the stomach the reverse being true in the digestion of cow's milk As a result of this physiologic fact the gastric juice of infants who are artificially fed is said to be less potent than that of breast-fed infants For this reason mother's milk, in spite of its early high fat content leaves the stomach more readily than does cow's milk

OBJECTIONS TO LONGER INTERVALS

The most serious objection entered against longer intervals of feeding in early infancy consists of the apparent necessity for administering too high quantities, as well as too rapidly increasing the strength of the milk mixtures in the artificially fed in order to maintain the required number of calories requisite for proper growth From the statistics previously recorded and in my own experience, these objections are based more on theoretical principles than on practical observations and results As Mosenthal has pointed out, the figures for gastric capacity, as they now are set forth in text-books, represent the anatomic capacity of the stomach, but the normal physiologic capacity, the amount of milk a child is capable of taking at one nursing, is considerably higher than these figures represent Holt has personally determined by post-mortem measurements the average capacity of the stomach in ninety-one infants from birth to the age of 14 months, but most careful clinicians have found that the amount of milk that can normally be ingested and digested has exceeded these average figures by from 1 to 3 ounces at the specified ages, especially so where the longer intervals have been employed Thus the average gastric capacities of infants at 1, 2 and 3 months of age are quoted respectively as 2, 3 37 and 4 5 ounces, whereas Caemerer recommends individual feedings of 3⅓ ounces (100 c c), 4⅓ ounces (130 c c) and 5⅔ ounces (170 c c) during these periods of infancy, employing the three-hour intervals and seven feedings a day during the first two months, and four-hour intervals thereafter These figures coincide essentially with my experiences As Caemerer further states, this is in marked contrast to the usual American two-hour interval, where the three-hour interval is usually not reached until the fourth month It is my firm belief that the results of the post-mortem findings relative to the capacity of the infant's stomach, in conjunction with the usual written and didactic teachings in reference to the size of milk-feedings, have had a strong tendency to make of the average practitioner a specific routinist in this connection

Several factors, both anatomic and physiologic, must be considered in computing the quantity of milk the babe may be fed at each nursing The stomach, which must be regarded as a dilated and specialized portion of the general intestinal tract, is provided with a submucosa of considerable thickness, composed of an abundance of fibro-elastic tissue which is loosely interwoven Unlike the intestinal tract elsewhere, its muscular tunic, in addition to the usual inner circular and outer longitudinal layers, is reinforced near the cardiac end by irregular bundles of oblique fibers Nature has evidently provided means whereby a certain degree of normal physiologic elasticity shall be allowed, thus easily permitting the accommodation of more contents than the post-mortem findings would seem to corroborate In early infancy, especially, it is an established fact that the contents of the stomach begin to leave it shortly after nursing has begun, thus in reality adding a portion of the pylorus to the actual capacity of the stomach That some infants have larger gastric capacities than others in direct proportion to their weight, other things being equal, seems at least reasonable If it be true, furthermore, that when shorter intervals are employed the stomach is not completely emptied when the next nursing is begun, a smaller relative "capacity" would naturally be expected at that time of nursing The utilization of any fixed rule governing the quantities for the individual feedings at various ages seems therefore impracticable My clinical observations, however, in common with others, have firmly established one undeniable fact, that the average normal child fed at longer intervals is able to ingest a larger quantity of milk than is usually prescribed, and invariably does so This is conclusively demonstrated by actually weighing the breast-fed babe immediately before and after nursing, as well as by the administration of larger feedings in the artificially fed and a resulting progressive increase of weight in both As a matter of fact, in my personal experience the usual normal maximum weight ordinarily attributed to the end of the first year is reached in many instances by the tenth month, and rarely later than the eleventh month, when the longer intervals of feeding have been judiciously employed Such evidence should certainly have a tendency to diminish any grave fears that the child fed at longer intervals is unable to receive a sufficient quantity of milk to meet its demands for growth and development

The same skepticism that exists in reference to the quantity prevails relative to the quality of the milk that must be employed It is widely stated that in order to satisfy the economy, when greater intervals of nursing are employed, the increased strength of the milk necessary to compensate for the diminution in the number of feedings would render it much more difficult to digest The fixed formulas variously recommended for the different periods of infancy have also been handed down, in many instances, in an empiric manner, and have frequently been responsible for an underfed baby at the hands of the automatic routinist In this connection also, each child must be a law unto itself, and only the most careful observations of the watchful practitioner should guide him in each individual case relative to the milk formula to be employed And here again, personal experience has shown that in the vast majority of cases infants fed at longer intervals obtain from the breast, and are able to digest when artificially fed, a milk of greater caloric value than the average baby fed at the shorter intervals can digest With few exceptions my artificially fed babies have received a 4-7-2 mixture by the fourth month and a 4-5-3 milk not later than the tenth month Such progress would be expected in consequence of the opportunity for complete evacuation of the stomach contents in addition to a much-needed period of absolute rest between each interval of apparently completed gastric digestion and the subsequent feeding It has been the rare exception, rather than the rule, that infants fed on the longer interval schedule have not been able easily to digest and thrive on whole cow's milk on or before the tenth month By the employment of the longer intervals, therefore, the above stated theoretical objections have been largely overcome, and the chief requirements in infant-feeding, namely, a quality of milk which is within the infant's power easily to digest, and a sufficient total quantity to assure a normal weight development, have been obtained

THE VALUE OF REST

Just as time and the resulting rest are absolutely essential for the fulfilment of good digestion, just so much, if not more so, is rest required for the progressive growth and development of the baby One well-known author, in common with many others, writes that "sleep is important for purposes of growth," and that "during the first month the infant sleeps about twenty-two hours out of every twenty-four" He then recommends ten nursings in the twenty-four hours, which will ordinarily consume a total of two to three hours Even though the function of nursing be a reflex one, in a great measure, the frequent disturbances necessarily produced by ten feedings, in addition to the wakefulness oftentimes produced during the daily attention to toilet, bath, etc, subtract largely from the rest the babe so much requires In the vast majority of babies fed at longer intervals, I have noted, in addition to the more rapid but uniformly progressive physical as well as mental development that the baby acquires a more decided resistance against the more common digestive disturbances, and even is less susceptible to the infectious diseases which so many mothers look on as being inevitable This acquired resistance, I feel, results largely from the more absolute rest which the child actually receives, in association with the resulting complete digestion and assimilation

SUCCESSFUL RESULTS OF LONGER INTERVALS

My own experiences with the longer intervals in milk-feeding during the first year have been uniformly and highly successful Although never guided by any fixed schematic feeding schedule, it has been my usual custom to recommend three-hour intervals in all healthy babes of the average normal weight, permitting seven feedings in the twenty-four hours, including the one night feeding Breast-fed babies are permitted to nurse until they are apparently satisfied, although usually a maximum of twenty minutes is ordered In the artificially fed, after the first four to seven days, a 2-6-1 milk is often prescribed, and an average feeding of 3 ounces is permitted, considerable emphasis being laid on the necessity for very slow nursing, and the extreme vigilance of the nurse in reference to discomfort, regurgitation, etc During the second, and rarely later than the third, month, being guided particularly by the digestive capabilities and the weight curve, four-hour intervals are ordered, permitting six nursings for the first one or two months, and five nursings thereafter As a general rule, a 4-7 2 mixture is reached not later than the fourth month, and a 4-5-3 milk by the ninth or tenth month, after which whole milk is generally employed In the healthy infant, weighing 9 pounds or more at birth, virtually the same general plan has been followed, except that the four-hour interval has been employed from the beginning, permitting six nursings in the twenty-four hours, until a natural rearrangement occurs, whereby one night nursing is volitionally dropped This often happens after the second or third month In these latter infants it has been my almost uniform experience that proportionately larger quantities as well as stronger formulas can be digested without any difficulty And the ease with which a four-hour interval can be established and maintained is surprisingly gratifying

The advantages of longer intervals in well-selected cases are numerous There is undoubtedly an almost total absence of even the mildest digestive disturbances, which would naturally be expected as a result of more complete digestion and assimilation Regurgitation is reduced to a minimum, if it is present at all, and vomiting is a rare occurrence The dreaded colic and constipation are far less frequent, and the weeping eczemas often resulting from gastro-intestinal auto-intoxication are rarely to be observed The infant develops a far better appetite, and obtains more as well as longer intervals of sleep, a pleasure and necessity which is appreciated and shared by the household There is in many instances even a better, and always uniformly progressive, gain in weight as compared with the average babe fed at shorter intervals Another, and by no means trivial advantage, associated th the longer in of
feeding is the com ith
ers can be infl
especially to tl
their babes wi

for them, but who, for domestic and especially social reasons, do not feel justified in foregoing certain duties and pleasures which frequent nursing would demand Once convinced that a three-hour, or a four-hour interval, will not be a compromise for her own convenience but rather a benefit to her infant, the number of nursing mothers will with certainty increase, as will the number of living and healthy babes

Before concluding, I wish to reiterate that no attempt has been made to advance a system of feeding that might be employed as a routine measure If sufficient interest in the employment of longer intervals of feeding in early infancy has been aroused to stimulate its more common usage in well-selected cases, I shall feel that I have not labored in vain

This paper would be incomplete without an expression of my most sincere appreciation of the kindness of the many physicians who supplied invaluable information through the circular letters sent to them, as well as an acknowledgment of my thanks to the committee who conferred on me the distinctive honor and privilege of appearing before you

ABSTRACT OF DISCUSSION

Dr H. Lowenburg, Philadelphia In reply to a letter from Dr Comroe, I said that I did not endorse long interval feeding, largely because my individual experience did not warrant it Dr Comroe would have us become as dogmatic with regard to the long interval feeding, as he accuses most physicians of being with regard to the shorter interval, as universally employed and as modified according to age Pediatrics has not escaped the chaos in which modern medicine finds itself It seems to be the predominant idea that we must present some thing new, that we must give up the old simply because it is old, its tried worth to the contrary notwithstanding Years ago it was taught that the great trouble with infant feeding was the protein element We all believed it and practiced it and had our successes and our failures Then it was taught that sugar was the disturber Some believed it and some did not Those who did, obtained good results, so also did those who did not believe Now fat is the cause and there are those who can prove it so and others who cannot. It is not wise to disturb the mental equilibrium of the practitioner or to give up the practice which has been successful in private and hospital work simply because of conclusions that are reached by experimentation, the purpose of which is to prove a preconceived idea We can prove almost anything we start out to prove I will not give up short interval feeding until there are better proofs as to the benefits to be derived from the long interval feeding My experience does not agree with Dr Comroe's He says that children fed at long intervals weigh more in a year than those fed at short intervals I can show case after case in which short interval feeding with proper food provides a steady increase in weight My own child at 8 months weighs 22 pounds Dr Comroe, however, strikes the key note of the whole feeding situation when he says that each infant is a law unto itself If we have a case of vomiting, it stands to reason that we are going to feed that baby at longer intervals in order to rest the stomach If the digestive process is normal, there is no reason to interfere

Dr D J M Miller, Atlantic City Some years ago I had the opportunity to pass the stomach tube into a number of infants, and as I found, as a rule, that the stomach was not empty until about two and a half hours after feeding, I have fed all infants of 3 months and over every three hours I agree with Dr Lowenburg that the methods which have brought success in the past are the ones to follow in the present I think that in cases of gastric indigestion with vomiting long interval feeding is decidedly beneficial With the ordinary healthy baby however I think that the method which has been the result of so many years of experience, intervals of two and a half hours, is the safe one to pursue under 3 months

Dr John L. Morse, Boston I want to protest against the accusation that the American pediatricians are routinists, meaning by American pediatricians those who follow the typical American methods rather than the European I do not believe that those who feed babies in the Eastern states are any more routinists in their methods than the Europeans and the people in the Middle West, who, as a rule, follow the European methods We are just as willing as anybody else to feed the individual baby—in fact, more so, as it seems to me from the literature The whole stress of Dr Comroe's paper has been toward routine rather than away from it I know that there is nobody in Boston who teaches and I do not believe that any of us here teach that a baby of a certain age should be fed any special mixture I also feel absolutely sure we in the East do not overfeed our babies and that we do not have the trouble that we are said to have Our babies do thrive I do not believe that in Europe or in the Middle West they can show babies more healthy or of better quality or with less digestive disturbances than we can with what is called a routine treatment, but what is really an individual treatment The average well baby if given reasonable food in proper amount in the twenty four hours will take care of it, whether fed once in two, three or four hours, some babies do better on four than two, others better on two than four But when the baby is sick, then the question of gastric or intestinal indigestion comes in and one has to regulate the intervals as well as the percentages of food It seems to me that we are both right, and perhaps we are both wrong

Dr. L T Royster, Norfolk, Va It has been said a number of times that the key note is struck in individualization, which I think is quite true The baby used as a laboratory is perhaps an uncertain guide as to practical feeding The anatomic content of the stomach is one thing and the physiologic content another Given two babies of the same age and the same weight, we find a different stomach capacity Perhaps the almost universal conception of the baby's stool is the one thing that may be a fair guide as to our conduct in feeding But we cannot feed the baby so many grams of food and expect so many grams of stool, in other words, the baby is not a test tube Again, when we come to the question of measuring the contents of the baby's stomach from the standpoint of a stomach tube, it is difficult Perhaps the best plan is to weigh it on a carefully balanced scale If the contents of the baby's duodenum can be secured through a catheter, it is also possible in measuring the contents of the baby's stomach after two or three hours of digestion to measure too much by getting into the duodenum

The Eastern pediatrician does not work by rule of thumb, and those whose work I have seen have shown just as much individualization in treatment as anyone else When I answered Dr Comroe's letter, I answered decidedly that I had no rule

Dr. David E English, Summit, N J I disagree with Dr Comroe on only one point I do not feed babies with any regularity that is, by the clock I think how soon a baby should be fed depends entirely on how it has disposed of its last meal A baby cannot always digest and assimilate the same amount of the same kind of food in the same number of minutes I think that a baby should be fed when absolutely nothing else will satisfy it, in other words, when it has thoroughly digested the last meal, when the stomach has had time to rest and contract, and when the baby has cried long enough, then is the time to feed it, and it should be fed full

Dr. J H Hess, Chicago Nobody has said that we should feed premature infants anything but breast milk And every one here has agreed that we must feed the baby individually Now when you have fed the baby individually and fed it breast milk, you have pretty nearly done the whole thing My paper, referred to by Dr Comroe, written some months ago was not advocating a method but was simply a retrospection of a series of patients to ascertain what they had been fed These babies had been fed individually what was seemingly needed to make each one gain in weight The records were preserved and some time after I went over them to see what we had accomplished We found that the babies weighing under 1,500 gm (and in my series eight of them weighed under 1,500 and only one weighed 2,000 gm) had been fed 120 to 140 calories on an average, those weighing over 1,500 gm about 110 to 130 calories These apparently were ideal cases I believe that premature babies to gain must be fed more than a normal baby In our cases, none of those weighing less than 1,500 gm gained on less than 90 calories Three and four pound babies commenced to gain on 70 calories Since that time, however I have been feeding less frequently I now use the three hour intervals up to the time that the infants reach what would be a normal weight, except in the very small ones, whom I still feed every two hours with diluted mixtures, and then lengthen he interval and make up calories by concentration

DR THOMAS S SOUTHWORTH, New York Although we realize that a number have made use of it on their own initiative in this country, a large part of the movement toward four hour feeding has come to us from Continental centers I think one reason is that it is better suited to the type of artificial feeding which the Continental men use It is very much better for the use of whole cow's milk It is also better for more concentrated mixtures than those which we ordinarily use here in short interval feeding In cases in which the breast milk is scanty, however, the long interval feeding would be disadvantageous because the breast needs more frequent stimulation to produce sufficient milk

DR. JOHN ZAHORSKY, St Louis The time in which a baby's stomach becomes empty depends on the amount given Of course, in an infant that gets only half an ounce, the stomach will be empty more quickly than in one who gets 5 or 6 If the baby gets only 1 or 2 ounces from the mother, its stomach will be empty in an hour and a half, and it will tell you so very emphatically When a baby is fed on a four hour interval it necessitates one night feeding until the baby is several months old When a three hour interval feeding is used one can soon do without a night feeding, which gives the mother a rest This I consider one of the advantages of a three hour interval feeding

DR ISAAC A ABT, Chicago I am from the Middle West and should like to make a suggestion I think that it is a mistake to feel that there is a Western and an Eastern pediatrist, we should feel that there is an American pediatry We should forever abolish any idea that there is any sectionalism or any feeling that one section is better or worse than the other

DR J H COMROE, York, Pa I have endeavored to make it clear that I am opposed to routinism, and in favor of individualism in the feeding of babies In Dr Lowenburg's reply to my communication, he stated that he had never employed the longer intervals, it must therefore be both presumptive and difficult for one having had no experience along this line to discuss intelligently a paper of this kind Eminent pediatricians throughout the United States and Canada, from both the East and West, show that they are getting away from the rigid intervals of two, two and a half and three hours It is reasonable to conclude that if in their experience such excellent results are being obtained with the employment of the longer intervals, the present dogmatic teachings, both in schools and in text books, should be revised.

Sterilization of the Unfit in Switzerland.—Schlub reviews twenty two cases in Switzerland in which operative sterilization of defectives was advocated by the legal or medical authorities or both, but for various reasons it was actually performed only in fifteen Five different cantons contributed to the list There has been no legislation on the subject and this is the reason why the authorities in some of the cantons have refused to apply the measure The case histories are summarized including the ultimate outcome and the views of various authorities are cited showing the growing general acceptance of the principle of sterilizing the morally unfit Schlub's study of the subject appeared in the last *Schweizerische Rundschau für Med*, 1912, xiii, 37

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK NEW AND NONOFFICIAL REMEDIES "

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W A. PUCKNER, SECRETARY

NOVATOPHAN—Novatophan is ethyl 6 methyl 2 phenyl quinolin 4 carboxylate, $CH_3C_9H_4N\,C_6H_5COOC_2H_5$, 6 2 4=$C_{19}H_{17}$ O N, the ethyl ester of Paratophan, (6 methyl 2 phenyl quinolin 4 carboxylic acid)

Novatophan is a slightly yellow odorless and tasteless crystalline powder melting at 76 It is insoluble in water but readily soluble in alkalies hot alcohol and strong acids

If 0 1 0 2 Gm novatophan be boiled for a short time with 0 5 Cc sodium hydroxide solution U S P then 5 Cc iodine test solution added and again heated, the odor of iodoform should be apparent

If novatophan be dissolved in concentrated sulphuric acid a light yellow solution results which on the addition of bromine water yields a reddish yellow precipitate

If ferric chloride be added to an alcoholic solution of novatophan a yellow not a brown color is produced (difference from Atophan and Paratophan)

Actions and Uses—The same as Atophan (New and Nonofficial Remedies, JOUR A M A, March 2, 1912, p 633) but it is practically tasteless

Dosage—Same as for Atophan

Manufactured by Chemische Fabrik auf Aktien (vorm E Schering) Berlin Germany (Schering & Glatz New York) No U S patent or trademark

Novatophan Tablets—Each tablet contains 0 5 Gm (7½ grains) novatophan

HEXAL—Hexal is hexamethylenamine salicylsulphonic acid $(CH_2)_6N_4C_6H_3(OH)COOH.HSO_3$

Hexal is prepared by the interaction of an alcoholic solution of salicylsulphonic acid and an aqueous solution of hexamethylenamine

Hexal is a white odorless crystalline powder readily soluble in water slightly soluble in alcohol and difficultly soluble in ether having an acid taste

If an aqueous solution of hexal be heated to 45 or 50 C formaldehyde will be liberated If the residue be now made alkaline with sodium hydroxide and again heated ammonia will be liberated

If to a dilute aqueous solution of hexal ferric chloride test solution be added a violet color will be produced

If to an aqueous solution of hexal an aqueous albumin solution be added a white precipitate will form If to an aqueous solution of hexal bromine water be added an orange colored precipitate will be formed

With the exception of the tannic acid test hexal responds to the identity tests of the U S Pharmacopeia for hexamethylenamine

If 0 2 to 0 3 Gm hexal be fused with 2 Gm fusion mixture (sodium carbonate and potassium nitrate) the resulting mass dissolved in hydrochloric acid the addition of barium chloride test solution will produce a white precipitate

If 0 1 to 0 2 Gm hexal be moderately heated with 5 Cc concentrated sulphuric acid a carmin red color will be produced

If calcium hypochlorite solution be added to an aqueous solution of hexal a brown color gradually appears

A 5 per cent aqueous solution of hexal should not be changed by saturation with hydrogen sulphide or the addition of barium chloride solution After acidulation with nitric acid the addition of silver nitrate solution should produce not more than a slight opalescence

Actions and Uses—It is claimed that hexal has the action of hexamethylenamine combined with an anesthetic and astringent action on the inflamed mucous membranes of the biliary passages and urinary bladder without having a deleterious effect on t [illegible] lls

Hexal is claimed [illegible] ns of the bladder and [illegible] vent bladder infection It is also claimed to be useful in pyelitis and pyelonephritis and in any diseased condition of the genito urinary tract due to bacterial invasion It is said to be useful in the treatment of uric acid diathesis and uric acid concretions in the kidneys and urinary bladder

Dosage—1 Gm (15 grains) three to six times daily dissolved in a glass of water

Manufactured by J D Riedel Aktiengesellschaft Berlin Germany (Riedel & Co New York) No U S patent or trademark

Hexal Tablets, 0.5 Gm—Each tablet contains hexal 0 5 Gm (7½ grains)

Therapeutics

DISTURBANCES OF THE HEART

(Continued from page 1889)

MALIGNANT ENDOCARDITIS ULCERATIVE ENDOCARDITIS

Since we have learned that bacteria are probably at the bottom of almost any endocarditis, the terms suggested under the classification of endocarditis as "mild" and "malignant" really represent a better understanding of this disease They are not separate entities, and a mild endocarditis may become an ulcerative endocarditis with malignant symptoms On the other hand, malignant endocarditis may apparently develop *de novo* Still, if the cause is carefully sought there will generally be found a source of infection, a septic process somewhere, possibly a gonorrhea, a septic tonsil or even a pyorrhea alveolaris Septic uterine disturbances have long been known to be a source of this disease Meningitis, pneumonia, diphtheria, typhoid fever and rarely rheumatism may all cause this severe form of endocarditis

Ulcerative endocarditis was first described by Kirkes in 1851, was later shown to be a distinctive type of endocarditis by Charcot and Virchow and finally was thoroughly described by Osler in 1885

Ulcerative endocarditis was for a long time believed to be inevitably fatal, it is now known that a small proportion of patients with this disease recover Children occasionally suffer from it, but it is generally a disease of middle adult life Chorea may bear an apparent causal relation to it in rare instances

Ulcerative endocarditis may develop on a mild endocarditis, with disintegration of tissue and deep points of erosion, and there may be little pockets of pus or little abscesses in the muscle tissue If such a process advances far, of course the prognosis is absolutely dire If the ulcerations, though formed, soon begin to heal, especially in rheumatism, the prognosis may be good, as far as the immediate future is concerned If the process becomes septic, or if there is a serious septic reason for the endocarditis, the outlook is hopeless This form of endocarditis is generally accompanied by a bacteriemia, and the causative germs may be recovered from the blood

If a more malignant form of endocarditis develops on a mild endocarditis the diagnosis is generally not difficult If without a definite known septic process malignant endocarditis develops, localized symptoms of heart disturbance and cardiac signs may be very indefinite

If there is no previous disease with fever, the temperature from this endocarditis is generally intermittent, accompanied by chills, with high rises of temperature, even with a return to normal temperature at times There may be prostration and profuse sweats Even without emboli there may be meningeal symptoms headache, restlessness, delirium, dislike of light and noise, and stupor, even convulsions may occur The urine generally soon shows albumin, there may be joint pains, the spleen is enlarged and the liver congested Some definite cardiac symptoms are soon in evidence, with more or less progressive cardiac weakness

Characteristic of this inflammation is the development of ecchymotic spots on the surface of the body, especially on the feet and lower extremities Sooner or later in most instances of the severe form of this disease emboli from the ulcerations in the heart reach the different organs of the body, and of course the symptoms will depend on where the emboli locate If in the abdomen, there are colicky pains with disturbances, depending on the organ affected, if in the brain, there may be paralysis, more or less complete If an infarct occurs in one of the organs of the body there must of necessity occur a necrosis of the part and an added focus of infection If a peripheral artery is plugged, gangrene of the part will generally occur, if the patient lives long enough

TREATMENT

If pneumonia or gonorrhea is supposed to be the cause of the endocarditis, injections of stock vaccines should perhaps be used If the form of sepsis was not determinable, streptococcic or staphylococcic vaccines might be administered It is still a question whether such "gunshot" medication with bacteria is advisable Patients recover at times from almost anything, and the interpretation of the success of such injection treatment is difficult Exactly how much harm such injections of unnecessary vaccines can produce in a patient is a question that has not been definitely decided Theoretically an autogenous vaccine is the only vaccine that should be supposed to be successful with our present knowledge The vaccine treatment of ulcerative endocarditis was not shown to be very successful by Dr Frank Billings in his investigation a short time ago[1]

Other treatment of malignant endocarditis includes treatment of the condition that caused it plus treatment of "mild" endocarditis as previously described, with the meeting of all other indications as they occur As in all septic processes, the nutrition must be pushed to the full extent to which it can be tolerated by the patient, namely, small amounts of a nutritious, varied diet given at three-hour intervals

Whether milk or any other substance containing lime makes fibrin deposits on the ulcerative surfaces more likely or more profuse, and therefore emboli more likely to occur, is perhaps an undeterminable question In instances in which hemorrhages so frequently occur, as they do in this form of endocarditis, calcium is theoretically of benefit Quinin has not been shown to be of value, nor has salicylic acid, unless the cause is rheumatism Alcohol has been used in large doses, as it has been so frequently used in all septic processes If the patient is unable to take nourishment in any amount, small doses of alcohol may be of benefit It is probably of no other value It is doubtful whether ammonium carbonate tends to prevent fibrin deposits or clots in the heart, as so long supposed In fact, whenever the nutrition is low and the patient is likely to have cerebral irritation from acidemia, whenever the kidneys are affected, or whenever a disease may tend to cause irritation of the brain and convulsions, it is doubtful if ammonium carbonate or aromatic spirit of ammonia is ever indicated Ammonium compounds have been shown to be a cause of cerebral irritation

---

[1] Billings, Frank Arch Int Med. November 1000 p 400

Perhaps the most advisable internal antiseptic treatment is that of hexamethylenamin This drug should be given in doses of 0 3 gm (5 grains), dissolved in plenty of water, once in six hours The administration of mercury in any amount or of the sulphocarbolates or any phenol preparation is probably of not so great value as hexamethylenamin Intestinal antisepsis may be attained more or less successfully by the administration of yeast or of lactic acid ferments together with suitable diet The nuclein of yeast may be of some value in promoting a leukocytosis It has not been shown, however, that the polymorphonuclear leukocyte increase caused by nuclein has made phagocytosis more active

Malignant endocarditis may prove fatal in a few days, or may continue in a slow subacute process for weeks or even months

CHRONIC ENDOCARDITIS

It is not easy to decide just when an acute endocarditis has entirely subsided and a chronic, slow-going inflammation is present It would perhaps be better to consider a slow-going inflammatory process subsequent to acute endocarditis as a subacute endocarditis, and an infective process may persist in the endocardium, especially in the region of the valves for many weeks or perhaps months, with some fever, occasional chills, gradually increasing valvular lesions and more or less general debility and systemic symptoms Such a subacute endocarditis may develop insidiously on a previously presumably healed endocardial lesion and cause symptoms which would not be associated with the heart, if an examination was not made Sometimes such a slow-going inflammatory process will be associated with irregular and intangible chest pains, with some cough or with many symptoms referred to the stomach, so that the stomach may be considered the organ that is at fault. There may be dizziness, headache, feelings of faintness, sleeplessness, progressive debility and a persistent cough, with some bronchial irritation and with occasional expectoration of streaks of blood, which may cause the diagnosis of incipient tuberculosis to be made In other words, the need of a careful general examination must be emphasized again before a decision is made as to what ails the patient, or before cough mixtures are given unnecessarily, quinin is prescribed for supposed malarial chills, or various diets and digestants are recommended for a supposed gastric disturbance

The term "chronic endocarditis" should be reserved for a slowly developing sclerosis of the valves This may occur in a previous rheumatic heart and in a heart that has suffered endocarditis and has valvular lesions, or it may occur from valvular strain or heart strain from various causes, it is typically a part of the arteriosclerotic process of age and is mostly manifested at the aortic valve

Rheumatism is the cause of most instances of cardiac disease which date back to childhood or youth, while arteriosclerosis is the cause of most cardiac diseases in the adult In the former case it is the mitral valve which is the most frequently affected, while in the latter it is the aortic valve Any cause which tends to induce arteriosclerosis may be a cause of chronic endocarditis, such as gout, syphilis, chronic nephritis, alcoholism, excessive use of tobacco, excessive muscular labor and hard athletic work Lead is also another, now rather infrequent, cause Severe infections may tend to make not only an arteriosclerosis occur early in life, but also a chronic endocarditis Heart strain may also be a cause of chronic endocarditis especially at the aortic valve Forced marches of soldiers, competitive athletic stunts, and occupations that call for repeated hard physical strain may all cause aortic valve disease Tobacco, besides increasing the blood-tension and thus perhaps injuring the aortic valve, may weaken the heart muscle and cause disturbance and irritation and perhaps inflammation of the mitral valve

There is no age which is exempt from valvular disease, but the age determines the valve most likely to be affected If endocarditis occurs in the fetus, it is the right side of the heart that is affected, in children and during adolescence it is most frequently the mitral valve that is involved, while in the adult or in old age it is the aortic valve that is most likely to become diseased Statistics have shown that the valves of the left side of the heart are diseased nearly twenty times as frequently as those of the right side of the heart They also show that the mitral valve is diseased more than one and one-half times as frequently as the aortic valve Early in life probably both sexes are equally affected with valvular disease, with perhaps a slight preponderance among females, because of their greater tendency to chorea Females also show a greater frequency to mitral stenosis than do males Aortic disease, on the other hand, from the very fact of their strenuous life and occupations, is nearly three times more frequent in men than in women

If a chronic endocarditis has followed an acute condition, some slight permanent papillomas or warty growths may be left from the healed granulating or ulcerated surfaces Sometimes these little elevations on the valves become inflamed and then adhere together or adhere to the wall of the heart, and thus incapacitate a valve Sometimes these excrescences undergo partial fatty degeneration, or may take on calcareous changes and thus stiffen a valve

If the chronic inflammation is not superimposed on an acute endocarditis there may be no cell infiltration and therefore no softening, but there is a tendency to develop a fibrillated structure, and a fibroid thickening of the endocardium occurs, especially around the valves This induration causes contraction and narrowing of the orifices with shortening and thickening of the chordae tendineae, and the valves imperfectly open, or no longer close Fatty degeneration may occur in the papillary growths with necrotic changes, and this may lead to the formation of atheromatous ulcers which may later become covered with lime deposits, and then a hard calcareous ring may form Fibrin readily deposits on this calcareous substance and may form a permanent capping, or may slowly disintegrate and allow fragments to fly off into the blood-stream and cause more or less serious embolic obstruction If this chronic endocarditis develops with a general arteriosclerosis, the same inflammation soon occurs in the aorta, and, following the endarteritis in the aorta, atheromatous deposits may also occur there Chronic endocarditis of the walls of the heart, not in immediate continuity with endocarditis of the valves, is perhaps not likely to occur, except with myocarditis

A subacute or a chronic infective endocarditis should be treated on the same plan as an acute endocarditis, which means rest in bed and whatever medication seems advisable, depending on the supposed cause of the condition

THE NERVOUS SYSTEM AND METABOLISM

The muscles, the secretory glands and the central nervous system preeminently represent the physiologically active tissues of the organism Their function exhibits itself in the familiar manifestations of movement, secretion and cerebration, respectively, but in the case of the muscles and glands, at least, there are well-known attendant phenomena characteristic of most physiologic activities in which a transformation of energy is concerned Heat is evolved and results in a transitory rise of temperature of the individual tissue or even the organism as a whole, carbon dioxid is eliminated in greater amounts, and this waste product serves as an index of the augmented chemical transformations going on while most striking of all, perhaps, is the increased consumption of oxygen—a typical indicator of heightened metabolism

Despite the obvious fact that the functioning of the higher nervous system must represent physiologic activity of a high order, it has been far from easy in the past to connect this with any of the evidences of metabolism so prominent and characteristic in the work of the other tissues mentioned As a result there has arisen the tendency to deny that nervous activities are accomplished with any demonstrable—or at all events, any noteworthy—transformations of energy The higher activities of the nervous system, such as are commonly termed "mental work," have rather been assumed to be characterized by a unique *quality* of participating change rather than by any measurable transformation of potential energy or quantitative metabolism of matter The make-up of the excreta has not been found notably altered after intense nervous response and the evidence for heightened gaseous exchange or respiratory metabolism is commonly considered to be negative

In accepting such conclusions respecting the apparent non-participation of the nervous system in the familiar augmentation of energy changes manifested by other tissues during their physiologic activity, it must be recalled that the nervous system comprises decidedly less than 5 per cent of the entire body It is accordingly quite conceivable that small increases in metabolism due to the greater work of this quantitatively minor organ might be hidden in the incidental variations due to the relatively great bulk of the other tissues Various investigators have insisted that the central nervous system makes an exceptionally large demand for oxygen on the circulation Lately Alexander and Révész[1] of Budapest have studied the gaseous metabolism of the brain, using optical stimuli as a mode of exciting the activity of this organ They reach the conclusion, apparently substantiated by their experimental findings, that the thus augmented function of the brain is attended with an increased consumption of matter and energy, evinced in the increased utilization of oxygen under such conditions of activity This result, of course is more in keeping with what a rational conception of the work of vigorously responding living cells would lead one to expect If this revision of current views will stand the test of future criticism and further experiment under even more crucial conditions, a supposed exception in the domain of physiologic functions will be eliminated

METHYL ALCOHOL AS A POISON

The history of toxicology furnishes repeated instances of the beneficial influence which accidental misfortune in the nature of obscure intoxication has indirectly exerted on the scientific study of poisons The widely discussed fatalities which occurred last winter in the neighborhood of Berlin as a consequence of the drinking of liquors which were contaminated with wood alcohol[2] served to direct attention again to the peculiar toxic character of methyl alcohol in contrast with the chemically closely related grain spirits, or ethyl alcohol As a consequence a number of valuable investigations have since been undertaken to elucidate some of the debated points in relation to the toxic action of alcohols

The German investigations of Voltz and Dietrich[3] were indicative of a minor participation of methyl alcohol in metabolism, in contrast with the ready combustion of the ordinary ethyl alcohol A further highly significant feature is the slow elimination of the wood spirits and its conversion products from the organism leading to a subtle danger in the form of accumulated toxic products France has now furnished further scientific data collected by Professor Nicloux and Dr Placet[4] Among the details of interest is the fact that for a single large dose (that is, acute poisoning) methyl alcohol may show a lower toxicity than does ethyl alcohol With either poison it is uniformly found that the brain retains more of the alcohol than do any of the other familiar organs, showing a sort of specific affinity in accord with what might be expected from its lipoid make-up The alcohols, like ether, chloroform and other volatile narcotics, are notably soluble in lipoids such as those characterizing the nervous system

When intoxication under chronic conditions, that is, with repeated small doses, is made the subject of consideration, however, the superior toxicity of methylated spirit at once comes into evidence This point was long ago emphasized by Hunt,[5] who noted that the great difference between the toxicity of methyl and ethyl alcohols might easily be overlooked entirely in experiments in which only the effects of single large doses were studied The French investigators, like their predecessors, have indicated anew that the probable explanation of the unduly pronounced poisonous character of the methyl alcohol is associated with the failure of combustion and the delay in elimination It has been suggested that the slowness in the removal of toxic products from the body may explain the onset of blindness which so frequently follows methyl alcohol poisoning in man, for, as Hunt remarks, highly differentiated nerve structures, such as those of the retina, are especially likely to suffer when exposed to the action of a poison for some time

With respect to the nature of the products, other than the unaltered methyl alcohol itself, which constitute the factors detrimental to health, it is impossible to give a final answer Pohl[6] has shown that the poisonous formic acid undoubtedly results and the production of formaldehyd as an intermediate product has also been suggested Methyl alcohol undergoes the same change in the human body as in that of the experimental animals, its administration to man led to the appearance of formic acid which was slowly excreted in the urine

Nicloux and Placet have raised again the question of the relative participation of by-products or impurities in the noxious effects of wood alcohol They believe that neither the slow elimination nor the possible accumulation of methyl alcohol and its derivatives are by themselves sufficient to explain the numerous cases of poisoning which have now been collected in the literature It is therefore logical to suggest that either man must be particularly susceptible to the toxicity of methyl alcohol, or impurities, which frequently accompany it, have a contributory share in producing the untoward results The "impurity" hypothesis has long assumed an unfathomed importance in numerous instances in which lack of knowledge or rather paucity of accurate information of all the factors, has driven an observer to seek a new explanation for his facts The impurities in anesthetics, the fusel oil in whisky, the furfural in tobacco-smoke — all have at various times been charged with a prominent share in some harmful experience It is true that some of these accessory factors are *per se* exceedingly toxic and detrimental, but the question and real possibilities of relative dosage are rarely worked out in a convincing fashion in the impurity arguments Without denying the possible importance of contributory accidental components, let us not overlook what is after all the fundamental point, namely, that chloroform, nicotin and ethyl and methyl alcohols are all poisons This fact must not be overshadowed by the more problematic possibilities of incidental impurities The paper by Dr Casey A Wood in this issue is a forceful reminder of the menace with which we are continually confronted in this country so long as the education of the public with regard to the dangers of wood alcohol is neglected and suitable legal safeguards are not provided and enforced

THE PHYSIOLOGIC EFFECTS OF COPIOUS WATER DRINKING WITH MEALS

Within the last five years much experimental work has been done by P B Hawk and his co-workers[1] in the effects on digestion and the metabolic processes produced by copious ingestion of water with meals Strangely enough, little work had been done on this subject previously, as the conclusion had been accepted on theory without experimental evidence that water taken with meals would dilute the digestive juices and hence would retard digestion Experiments on dogs proved that the ingestion of quantities of water with food caused a marked increase both in the quantity of the gastric juice and in its hydrochloric acid content Further, a dog could fast longer with less loss of weight and strength if allowed an abundance of water This indicates that water promotes economical metabolism

Hawk then carried out a series of experiments in which healthy young men were put on a uniform diet and their food and excreta analyzed quantitatively The experiments were divided into three periods a preliminary period, during which the subjects were brought into a condition of approximate nitrogen equilibrium by several days of uniform diet and light exercise, the experimental period, during which definite quantities of water were added to each meal, and a period during which the effects of the experiment were watched for a number of days with uniform diet without the added amount of water In some cases 500 c c and in other cases 1,000 c c of water were taken with each meal in addition to the daily amount of water normally taken The subjects were weighed daily and analyses made of the excreta collected as twenty-four-hour specimens

An expected result was the immediate increase in the quantity and decrease in the s[illegible]ty of the urine

Accompanying this was a decided increase in the ammonia-nitrogen and chlorin excretion Hawk explains this as a result of the increased secretion of hydrochloric acid by the stomach due to the stimulating effect of the water This acid, being neutralized by the ammonia formed as a result of protein consumption in the tissues, gave the increased output of ammonia and chlorin, probably as ammonium chlorid There was also a decrease in the uric acid content and an increased allantoin output which is tentatively attributed to the more complete oxidation of the waste products Analyses of the stools showed a decrease in the fecal output both wet and dried This was accompanied by a decrease in the fats and carbohydrates excreted, in the fecal nitrogen and in the actual bacterial content The intestinal putrefaction was decreased as measured by the indican output This is ascribed to the inhibition of the indol-forming bacteria due to the accelerated absorption of the products of protein digestion More complete absorption of all foods leaves less culture medium for bacteria, which may explain the decrease in fecal bacterial content Though the nitrogen of the urine was increased, the fecal nitrogen was decreased and quantitative analysis of the total nitrogen ingested and excreted showed that the body was storing nitrogen In other words, the system was laying up protein material All this would indicate that the digestion, absorption and economical utilization of proteins, fats and carbohydrates had been promoted by ingestion of water with meals

The amylolytic activity of the feces, denoting, according to Wohlgemuth, the content of pancreatic ferment present, was increased over that of the period of average water ingestion Hawk interprets this reservedly as indicating a stimulation of the pancreatic function

The subjects showed increase in body weight and a general improvement in physical and mental condition There were many desirable and no undesirable results The effects were more pronounced when larger quantities of water were taken The results were not temporary but persisted after the close of the experiment As suggested previously in these columns,[2] the copious drinking of water with meals should not be practiced indiscriminately Certain pathologic conditions would be a distinct contra-indication to copious water-drinking Also experiments have established that digestion is retarded until the stomach contents have been brought to the body temperature Hence large quantities of very cold water would be distinctly non-beneficial It would be of interest to know whether equally favorable results would follow if the increased amount of water were taken between meals instead of with meals As the matter stands, the experimental evidence seems to refute the theories previously held regarding the effect of water taken with meals

ARTERIAL HYPERTENSION AND DIET

Heightened arterial tension is a phenomenon of increasing frequency among the population of civilized countries It is making its appearance at an earlier age with the progress of the decades Wherever hypertension is recognized, it is looked on as the sign of an impending arteriosclerosis, the more pronounced features of which may still be in a latent stage This symptom, which is yearly more adequately recognized in its incipient form, owing to the introduction of improved clinical methods of measuring blood-pressure demands earnest consideration because of the suggestion of forthcoming pathologic dangers which it furnishes

Various causes of arterial hypertension, whether assumed or demonstrated, are too familiar to need rehearsing in detail here It should always be remembered that the rise in blood-pressure is in no sense the immediate disease factor, but presumably rather of the nature of a compensatory function related to some less apparent ulterior cause The customary treatment consists in eliminating, as far as possible, such alleged etiologic factors of arteriosclerosis as can be associated with the individual under consideration The undue use of the various types of stimulants — alcohol, coffee, tobacco and the like — is prohibited Dietary indiscretions are avoided in so far as they are recognized, and various manifestations of neurasthenic temperament or nervous strain are subjected to such discipline as individual circumstances seem to dictate Much of this story has been repeated time after time, along with the prescription of mild forms of physical therapy of the most diverse types, such as baths, gentle exercise and massage

The immediate reason for referring to this subject again is to review a report of the management of a large series of cases of incipient arterial hypertension in which the careful regulation of the diet formed the most essential factor and seemed to be productive of beneficial results if one may judge by the index of blood-pressure measurement[1] The special feature of the treatment as it is conducted in one of the European sanatoriums consists in the restriction of meats, fluid intake, alcohol, salt and spices, and the encouragement of the use of fresh vegetables The physical methods take a secondary place in the regimen of the patients The comparative blandness of a diet devoid of the ordinary stimulating elements is in itself a help in controlling the excessive appetite that attends so many of the typical subjects It is, in fact, one of the salient features of a vegetarian regimen which is often prescribed for individuals who exhibit manifestations of hypertension Overeating is thus averted by means that seem less drastic to the patient than does the more direct proscription of favorite foods Attendant corpulence may be successfully reduced by the same procedure

[2] Water Drinking with Meals editorial The Journal A M A Jan 13 1912, p 117

[1] Compare Hecht A Ueber die diätetische Beeinflussung pathologischer Blutdrucksteigerungen, Ztschr f klin Med 1912 lxxvi 87

The reduction in the intake of fluids, especially the limitation of large amounts of water so often taken with meals by persons accustomed to rapid eating and insufficient mastication of highly seasoned dishes, has repeatedly been demonstrated to result in a fall of blood-pressure from an unduly high level. Pronounced diminution in the amount of salt consumed leads to a similar result by decreasing the customary thirst associated with the excessive use of dietary adjuvants of this sort. Doubtless the ingestion of salt is enormously overdone in certain quarters and the habits of man in this respect are subject to striking variations. Combined with all these precautions is the advice to distribute the meals in a way that will avoid undue hunger or thirst at any time and thus prevent the consequent tendency to momentary errors or extravagances in eating.

The foregoing precautionary suggestions are in the main bits of wisdom self-evident to any one who appreciates at all the physiologic possibilities of rational dietotherapy. As yet however dietetics is far from receiving the consideration which is merited by its potent influence in certain types of disorders. Perhaps the assurances now available in a long series of published records will encourage a greater interest in the appropriate ordering of the diet along with other better appreciated curative and prophylactic measures when the earliest symptoms of arterial hypertension begin to manifest themselves.

INFANTILE BERIBERI

Among those who have little occasion to come into personal contact with the manifestations of beriberi this disease is customarily considered a malady of adults or adolescents. In the Far East where, because of its wide prevalence and serious inroads into the health of large communities, beriberi is now more effectively studied and controlled, the existence of what may properly be termed "infantile beriberi" has been recognized for some time. Two factors have of late directed particular attention to this manifestation in earlier life: the wide-spread interest and extensive investigation which beriberi has engaged everywhere, and the high death-rate among infants, particularly in the Philippines, where the subject of infant mortality has aroused considerable professional concern. Prior to the present correlation of beriberi with deficiencies in the diet, the interpretation of the symptoms in early life was under the dominance of the views then current respecting its etiology. Infantile beriberi, presumably identical with the sickness termed *taon, taol* or *suba* by the native laity, is common in children nursed by mothers suffering from beriberi. Accordingly one theory which was advanced to explain the rapid onset and severe character of the infantile manifestations attributed these to a toxin transmitted in the mother's milk.

Professor Andrews of the department of pathology in the University of the Philippines is engaged in a study of the facts bearing on infantile beriberi, and has pointed out some of the difficulties in its management which are attributable to conditions obtaining in the tropics.[1] His observations bring out clearly that the disease is not due to an infection or toxemia of either the mother or the child. All the evidence available is in complete harmony with the generally accepted view that beriberi is a nutritional disturbance. In fact, the special features which pertain to the infantile variety of the disorder, and particularly the conditions under which they arise, strengthen the current malnutrition hypothesis.

Actual analyses of the milk of mothers who are nursing sick children disclose no quantitative deficiencies in the mammary secretion so far as the familiar constituents are concerned. Infants improve rapidly after a change of diet — too rapidly to make it likely that the disease is due to bacteria in the milk. Highly significant is the fact that it was possible to produce in puppies incoordination and weakness of the extremities, degeneration of peripheral nerves, edema and anemia of the subcutaneous tissues — all symptomatic of infantile beriberi — by feeding the growing animals with the milk of mothers who had nursed affected children.

The unfailing correlation of the infantile disease with the corresponding illness of the mother lends effective significance to the conclusion that the mother's milk is probably deleterious because of what it lacks rather than because of any harmful constituent. Although occasionally the symptoms in the mother are not apparent at the time the disease manifestations appear in the suckling infant, they are likely to appear if the child continues nursing. The Manila investigator states that occasionally a mother is found showing symptoms of the disease while the child is apparently free, but on continued watching symptoms will be observed to appear in the infant. The history of the mother shows that invariably her diet consists of polished rice and fish or meat, rarely of a vegetable or any fruit. The mortality statistics indicate that infantile beriberi is more prevalent in the wet season in the Philippines. The probable explanation rests in the fact that fresh vegetables and fruits are scarcer at this time, prices go up with a consequent shutting off of the supply to those poorer classes who particularly require these products.

Inasmuch as the incidence of infantile beriberi is associated with the quality of the mother's milk, and as artificial feeding is not a possibility under the circumstances which prevail at present, attention must be centered on the corrective nutrition of the mother. Professor Andrews has *pointed out clearly that the* improvement of the physical condition of the Filipino mother and of the quality of her milk is a most important economic question. Half of the deaths among Filipinos in Manila are of infants during their first year of life. Fifty per cent. of these are due to infantile beriberi. Time after time, it is stated, a mother has had five or six children, all of whom have died of this disease. The incidence of death here is the more striking because in more advanced populations it is precisely among breast-fed infants that the mortality is relatively small, whereas in Manila 75 per cent. of the deaths of infants have occurred among the breast-fed.

---

[1] Andrews, Vernon L.: Infantile Beriberi, Philippine Jour. Sc., Sec. B, The Philippine Jour. Trop. Med., 1912, vii, 67.

How to bring about reform and relieve such a situation needs to be seriously debated. Andrews suggests that as a prophylactic measure the dealers handling rice should be required to keep on hand the undermilled variety, and that a campaign of education should be carried on for the purpose of enlightening the poorer classes, especially the pregnant women among them.

TRACHOMA IN THE UNITED STATES

Trachoma is supposedly a disease of oriental origin. Passages have been found in ancient Greek and Egyptian writings which presumably refer to it. From Asia it is supposed to have extended into Northern Africa and later into Europe. The disease is to be found at present in all parts of Europe, but particularly in certain parts of Russia and Poland, in Galicia, Austria-Hungary, in Italy and in Greece. In the two countries last named, it has been of common occurrence for some time. Prior to 1897 various observers had invited attention to the increasing prevalence of trachoma in the United States, cases were frequently met in our cities, and outbreaks of the disease, especially among schoolchildren, had been occasionally reported. The incidence of the disease seemed to be limited largely to the alien population and recently arrived immigrants. As a large proportion of the immigrants coming to this country are from the localities in southern Europe where the disease is common, in 1897, for purposes of immigrant inspection, trachoma was classed among the dangerous, contagious diseases, with the result that the finding of this affection in an arriving alien makes mandatory his deportation under the immigration laws.

For some time it has been known that trachoma was present to a considerable extent among our Indians. Clark of the United States Public Health Service during the past summer found many cases on the reservations in Minnesota. These findings were deemed by the Minnesota State Board of Health to be of sufficient importance from a sanitary point of view to warrant the board in giving the matter the most careful consideration with a view to formulating plans for preventing the spread of the infection. Such action was clearly indicated for the protection of the commonwealth, trachoma being a communicable disease, mutilating in its effect, reducing markedly the efficiency of those affected, and, unless properly treated, ending frequently in blindness.

Recently McMullen,[1] also of the Public Health Service, in an investigation of the *prevalence of trachoma in* eastern Kentucky, undertaken at the request of the Kentucky State Board of Health, found a most unlooked-for and surprising condition. McMullen carried on his survey in the mountain districts in Knott, Perry, Leslie, Breathitt, Lee and Owsley counties, and in the blue-grass country in Clark County. He examined in all 3,974 people, of whom 500, or approximately 12.5 per cent., were found to have trachoma. Of those examined, 2,796 were schoolchildren from the mountain counties, and of these 338, or approximately 12 per cent., had the disease. In Clark County, on the other hand, which is in the blue-grass country, and in which living conditions are quite different from those in the mountains, only fifteen cases of trachoma were found among 436 schoolchildren examined.

The conditions found in Knott County may be taken as typical of those existing in the mountain counties. In this county twelve schools were visited and 659 schoolchildren examined. Of these, 119, or more than 18 per cent., had trachoma. Outside of the schools 400 people were examined and 102 cases of trachoma found. McMullen explains, however, that among these 400 examined were many who had come for examination because of sore eyes, and for this reason the 102 cases among 400 examined constitute undoubtedly a higher morbidity-rate than exists generally. In this county a total of 1,059 people were examined and 221, or approximately 20 per cent., were found to be affected with the disease, and McMullen estimates that between 8 and 10 per cent. of the entire population are suffering from trachoma. Similar conditions were found in the other mountain counties. The population of this region consists largely of people of small means, descended from Anglo-Saxon stock, who have lived in the locality for several generations. Most of them live in simple, small cabins, and the country is sparsely settled. According to McMullen, these cabins often consist of but one room in which the entire family, numbering frequently from ten to fifteen, and averaging about eight, sleep. Usually all members of the family use one towel, which is made to serve for a number of days before being relaundered. The cabins usually have insufficient window space, many of them having but one small window, and some of them none at all. McMullen states that the source of the original infection among these people is obscure, but that the disease has been among them beyond the recollection of the oldest inhabitants.

The finding of a communicable disease of the nature of trachoma so prevalent in a community places it among the commonwealth's important public health problems. A locality cannot continue heavily infected with such a disease without constituting a serious menace to neighboring uninfected localities and to localities even more remote. It is probable, however, that the conditions found in Kentucky do not exist in that state alone, but that investigation would show similar conditions present in the contiguous mountain regions of West Virginia, Virginia, Tennessee and North Carolina. McMullen suggests that measures to remedy the condition should be directed toward the prevention of the spread of the disease and the treatment of existing cases. At best, however, the problem is one that will take some time to bring to a satisfactory solution. It will require the utmost efforts of the authorities, assisted by the cooperation of the people.

Current Comment

MONGOLIAN BIRTH MARKS—THE "BLUE SPOT"

Recently Wigglesworth[1] has noted that the Navajo Indian babe invariably has a "blue spot" over the sacrum. A blue spot in this location was first mentioned by Bealz,[2] who found it in Chinese, Japanese, Malays and Koreans. Fink[3] saw such patches in the Burmese, and Castor[4] in a discussion of Fink's work, corroborates his statements and concludes that the spots are atavistic. The pigmented patches over the sacrum vary in size from a quarter-dollar to a hand's breadth and superficially they resemble closely the bruises received from a fall. They may disappear within the first few years of life, but may be present in later years. Fink found them in 94.7 per cent. of Malay children. They are not nevoid in type but purely pigmentary. These spots bear no relation to abortive types of spina bifida, although they have been associated in isolated cases with this disorder. In some cases when the mother was of Mongolian type the spots were present with certain other Mongolian characteristics, such as the third eyelid. Consiglio has found such blue patches on about 2 per cent. of children in northern Italy and believes them to be attributes inherited from ancient Mongolian ancestors. Wigglesworth states that the Navajo Indians are supposed to have migrated from Asia, and by language tests ethnologists have been able to trace them as far as Alaska. The value of the spots as a mark of identification is not determined. Bruch,[5] who studied the occurrence of the mark in Tunis, Africa, found it quite common among the children there but only in brunette types. He states also that the blue spot has been noted in Europeans, but very rarely. Other observers also assert that the spot is not peculiar to Mongolian races. Apes and monkeys are said to have it constantly and throughout life. Possibly the blue spot might be found in negro babies if examined soon enough after birth before the skin becomes too dark, as suggested by Bruch. Evidently further and more extended observations are necessary in order to determine definitely whether the spot is to be given any special significance.

TRANSPLANTATION OF DURA MATER

Observations which have lately been made in the Physiologic Institute of the University at Vienna suggest the possibility of employing the dura mater successfully in surgical technic, for the purposes of homoioplastic and heteroplastic transplantation. The strength, elasticity and texture of the dura from various regions of the nervous system of man and higher animals have been measured with satisfactory assurance of the qualities which are a desideratum for the specific practical uses noted.[1] There are differences in the thickness of the membranes of different species, and the variations appear to be correlated with unlike degrees of development in the parts of the cerebrospinal nervous system. Boiling with water is detrimental to the make-up of the dura, but it can be preserved satisfactorily by fixation in formaldehyd solution and alcohol without serious detriment to those textural qualities which make it suitable for sterile implantation. It has been suggested that the product is especially adapted for replacement in defects of the dura. The resistance of the material to absorption gives it an added virtue for such purposes.

EXPERIMENTAL RHEUMATIC MYOCARDITIS

Among the lesions more or less characteristic of articular rheumatism are the nodules in the myocardium first observed by Romberg and by Bret, and studied more fully by Aschoff, Coombs, Fraenkel and others. Briefly, it concerns minute, discrete foci of embryonal cells and leukocytes that arise especially about the smaller vessels of the heart muscle. They appear to occur most commonly in the subendocardial parts of the septum, and in time they may change into scars. Fraenkel[2] found them in seventeen or twenty cases with a history of rheumatism, failing to find them in other infectious diseases he concluded that they occurred only in genuine rheumatism, although not necessarily in every case. It is interesting to note that Fraenkel doubted the streptococcal nature of rheumatism because streptococci, though reproducing the picture of rheumatism in rabbits, had not been shown up to the time of his writing to cause myocardial nodules in this animal. In view of the fact that his own observations indicated that the myocardial nodules may not occur in all cases of rheumatism it might be questioned whether their absence in rabbits injected with streptococci should be entitled to such significance. Recently, however, it has been demonstrated by Wächter, by Bracht and Wächter, and by Leila Jackson[3] that the injection of rabbits with streptococci from various sources does produce focal myocardial lesions similar to those found in the human heart in articular rheumatism. The streptococci used by Jackson in her experiments were obtained from the various forms of streptococcus infection of the milk epidemic in Chicago last winter and in Boston the year before. In these epidemics joint involvements were not infrequent, more or less typical cases of acute rheumatism occurred, and in many of the rabbits injected with the streptococci, arthritis also developed While it would be desirable to repeat the experiments with strains of streptococci from typical cases of articular rheumatism[3] the results already obtained, especially those by Jackson in which distinctively rheumatic myocardial foci were produced, support the view that streptococci cause acute rheumatic fever, or at least play a definite part in the process

THE POTENCY OF THYROID GLAND PREPARATIONS

The therapeutic efficiency of preparations of the thyroid gland has of late been correlated with the iodin complex present in the gland No other iodin-bearing compound, either organic or inorganic, seems to exhibit quite the same degree of potency in those cases in which the peculiar and characteristic influence of thyroid medication is to be evoked Iodids and organic iodin compounds are widely used for certain therapeutic effects not directly related to the glands here in question It is not to these applications that we refer, but rather to the effects associated with organotherapy The products available in the form of desiccated thyroid are derived from several of the slaughter-house animals notably sheep and the preparations sold are now frequently "standardized" in terms of their content of iodin A recent examination of glands from animals in the Chicago stock-yards[1] showed with reference to size relations that the small glands of all the animals studied — sheep, beef, hogs — usually contain the most iodin With respect to the species, the glands of hogs are uniformly richest in iodin so that their selection for therapeutic purposes appears decidedly rational It would be advisable, however, to learn the influence of the previous diet of stock-yard animals on the iodin content of the thyroids, and to have data derived under a wider range of feeding, before the comparative merits of the three species mentioned are brought into too bold contrast At least there is no occasion at present to reject the hog products

Medical News

ARIZONA

New Society—The Greenlee County Medical Society was organized October 19 with a charter membership of fourteen Dr A M Tuthill Morenci, president, Dr E R McPheeters, Clifton, vice president Dr Edward N Reed, Clifton, secretary and Dr L A W Burtch, Clifton, Treasurer

New Hospitals—Ground was broken November 5 at Safford for the Arizona Sanatorium which is to cost about $125 000 ——The new administration building of the Arizona State Insane Hospital, Phoenix, a two story and basement building of concrete and brick construction, fire proof and offering accommodation for the executive officers and living quarters for the superintendent, has been turned over to the state

Personal—Dr and Mrs Francis H Redewill, Phoenix, have returned after a ten thousand mile automobile trip ——Dr H K Beauchamp, Phoenix, formerly superintendent of the Arizona Asylum for the Insane, has returned after a sojourn for six months in the East ——Dr Warren E Day has resigned as house physician to the Pioneers' Home, Prescott ——Dr F W Randall, health officer of Douglas, has been appointed registrar of vital statistics

ARKANSAS

New Officers—Arkansas Medical Association (colored) annual meeting, in Little Rock president, Dr J G Thornton, secretary, Dr G W Ish, both of Little Rock Hot Springs was selected as the next place of meeting

Personal—The residence of Dr J C Land, Walnut Ridge, was burned October 31 with a loss of about $5,000 ——Dr Charles S Holt, Fort Smith, has been appointed division surgeon of the Missouri Pacific Iron Mountain Railway, his district extending from Van Buren, Ark., to Coffeyville, Kan, and including the Greenwood branch Dr Phillips has been appointed local surgeon of the road at Van Buren vice Dr Edward C Wittwer, resigned ——Dr W H Blankenship, Pine Bluff, was painfully injured in a collision between his buggy and an automobile, October 1 ——Dr C B Paddock, Fayetteville, sustained severe bruises of the head and neck by the overturning of his automobile, recently ——Dr James L Dibrell has been appointed a member of the State Board of Charities, vice Dr Edward R Dibrell, deceased ——Dr Gaston A Hebert, Hot Springs, has been elected by the council, president of the Arkansas Medical Society, vice Dr E R Dibrell, Little Rock, deceased

CALIFORNIA

Psychopathic Ward for County Hospital—Architects have been asked to submit plans for a new psychopathic ward at the Los Angeles County Hospital

Medical Building for San Diego—Plans have been made for an eight story, concrete, reinforced office building designed especially for the use of physicians and dentists

Leper Returned to Hawaii.—A Hawaiian mess attendant on the battleship *Connecticut*, found to be suffering from leprosy, was transported across the continent and is being held in a tent near the Mare Island Navy Yard Hospital awaiting transportation to the leper colony at Molokai

Health City for Los Angeles County—Los Angeles County is planning to establish a county health city in the mountains, consisting of fresh air cottages where tuberculosis patients now being cared for at the county hospital, may have better chances for recovery and health The county plans to spend about $75,000 on this project

Personal—Prof Arthur Schattenfroh of the chair of hygiene in the University of Vienna, who is making an inspection of municipal sanitation in the United States, visited Los Angeles recently, and was the guest of the health commissioner, Dr L M Powers ——Dr P G Cotter, Los Angeles, had several ribs broken and was otherwise seriously injured in a collision between his automobile and a trolley car, November 4 ——Dr K C Gummess, Los Angeles, was attacked by four hold up men November 4 and robbed of his valuables and most of his clothing ——Dr Elizabeth F Kearney, Los Angeles, has returned from abroad ——Dr Charles Lincoln Edwards has been appointed professor of embryology and histology in the Medical Department of the University of Southern California, Los Angeles, and has been made director of the department of nature study in the Los Angeles public schools

COLORADO

New Sanatorium for Denver—A sanatorium of national scope is planned to be erected near Denver under the auspices of the Roman Catholic Church for the benefit of the people of that faith suffering from tuberculosis

Personal—Dr Allison Brown, Denver, has been appointed acting assistant surgeon in the U S P H Service with station at Fort Stanton, N Mex ——Dr R C Montgomery, Meeker, was painfully injured by the overturning of his automobile ——Dr H E Abrahams, Trinidad, was seriously injured by a fall from a twenty five foot ledge while deer hunting in the Chaquaque country ——Dr Mary Arnett, formerly of Boulder, has started from Honolulu on a trip around the world ——Dr Carroll E Edson Denver, has been appointed a member of the Public Library Board ——Dr Wilbur Lowe, Denver, was operated on for appendicitis in Mercy Hospital, November 2 ——Dr J Ed Ray, Sugar City, who has been seriously ill in St Mary s Hospital, Pueblo, is reported to be slowly improving

---

[3] This has just been done by Coombs Miller and Kettle (Lancet 1912 clxxxiii 1209) and with the same results apparently as Jackson

[1] Aldrich T B The Iodin Content of the Small Medium and Large Thyroid Glands of Sheep Beef and Hogs Am Jour Physiol, 1912 xxxi 125

ILLINOIS

Site for Sanatorium Donated—The president of the Board of Commissioners of Cook County has donated to the county twenty five acres of land joining the Oak Forest Infirmary, to be used as the site for a county tuberculosis sanatorium

Personal—Dr J R Rigg, Mount Pulaski, fell into a cellar recently and fractured a rib ——Dr William E Rice, Tuscola, has been elected coroner of Douglas County ——Dr W B Hughie has succeeded Dr George M Peairs as surgeon of the Illinois Steel Company at Joliet ——Dr Edward H Lane, French Village, was seriously burned by the explosion of a gasoline lamp, November 13 and is a patient in St Vincent's Hospital, Belleville

Chicago

Personal—Dr Charles Porter Small, who has been physician of the University of Chicago since its founding, has resigned ——Dr Arthur D Bevan was painfully injured in a collision between his automobile and a cab, November 20

Consulting Staff for Coroner—Coroner Peter M Hoffman of Cook County has named the following as members of his consulting staff Drs John H Long, Walter S Haines, Ludvig Hektoen and John A Wesener and Chief Justice Harry Olsen of the Municipal Court By the aid of this consulting staff and the establishment of a chemical laboratory the coroner hopes to reduce the number of fatalities from poison which annually swell the list of deaths registered as "suspicious" requiring investigation by the coroner

INDIANA

New Officers—Union District Medical Society at Rushville, October 24 president Dr James E Morris Liberty, secretary, Dr David W Stevenson, Richmond

Small Pox.—Small pox is said to have existed in Jasonville for more than six weeks and to have been carried to Worthington from that place Dr J N Hurty health commissioner, visited these cities November 15 to investigate and direct measures for the suppression of the epidemic

Personal—Dr W A. Gekler has been appointed superintendent of the State Tuberculosis Sanatorium, Rockville ——Dr A W Brown has been elected superintendent of the Bluffton Branch of the Indiana Association for the Study and Prevention of Tuberculosis ——Dr A L Spinning Covington, has been appointed city health officer, vice Dr J R Hicks ——Dr John M Cunningham has succeeded Dr E B Mumford as inspector of contagious diseases for the Indianapolis Board of Health ——Dr John A Axline, Noblesville has retired after thirty nine years of practice ——Drs George W McCaskey, Miles F Porter, B P Weaver and Miles F Porter, Jr, have secured offices and laboratories in the Physicians' Defense Building, Fort Wayne ——Dr W W Barnett, For Wayne, announces that he is going to Cuba for a visit of four to six weeks ——Dr Samuel Hollis, Hartford City, has been elected president and Dr James A. Taylor Montpelier, a vice president of the Blackford County Association for the Study and Prevention of Tuberculosis ——Dr H H Martin, Laporte, has returned from Europe ——Dr M C Wilson has succeeded Dr Frank S Crockett, resigned, as meat and milk inspector of La Fayette

KENTUCKY

New Officers—Hardin County Medical Society, at Elizabethtown November 14 president, Dr H R Nusz Cecelian secretary treasurer, Dr E J Strickler, Elizabethtown

Small Pox Decreasing—The epidemic of small pox which has been prevalent in Sebrie for the past six weeks is subsiding, and about half of the patients who had been placed in quarantine have been released

Prison Farm for Tuberculosis—The Board of Prison Commissioners hopes in the near future to establish a state farm where prisoners suffering from tuberculosis may live in the open air and have a chance for their lives At Eddyville a new hospital has just been completed and arrangements have been made for a tent colony on the roof where prisoners suffering from the disease may live either in tents or in the open air, and thus far the experiment has been satisfactory

Hookworm Disease in Kentucky—It has been reported to the State Board of Health that since December, 1911 the state inspectors have treated 5 025 persons suffering from hookworm disease, and that 4,058 have been treated during the quarter ended Sept 30, 1912 Under the joint auspices of the Rockefeller Commission for the Eradication of Hookworm, the Kentucky State Board of Health the Jefferson County Board of Health and the Fiscal Court of Jefferson County, a series of illustrated lectures will be given at different towns in Jefferson County by Dr W W Richmond, Clinton, who is associated with the Rockefeller Commission Dr B W Smock Louisville, county health officer of Jefferson County will accompany Dr Richmond During the Child Welfare Exhibit in Louisville this week, Dr Richmond delivered a lecture at the Armory, November 25

LOUISIANA

New Officers—St Tammany Parish Medical Society, organized at Covington, October 30 president, Dr H E Gautreaux, Covington, secretary, Dr H D Bullock, Folsom

Needs of Dispensary—Pleas have been made to the New Orleans city council for an appropriation of $5 000 for the New Orleans Dispensary, of $15,000 for the Touro Shakespeare Alms House and of $15,000 for the Society for the Prevention of Cruelty to Children

Hospital and Infirmary Notes—The Touro Infirmary, New Orleans, has asked the city council for an increase of $4 000 in its appropriation, as in its charitable work the institution has contracted debts amounting to $21 000 ——The new Crowley Sanitarium is now ready to receive patients The institution contains nineteen ward rooms and two private suites operating rooms, reception rooms, etc ——Tulane University is equipping a modern emergency hospital on the campus to provide for any case of illness or emergency which may arise among the students The building will accommodate eight patients

For the Betterment of the Medical Corps.—The adjutant general of Louisiana has completely reorganized the medical and hospital corps of the National Guard of the state along the lines suggested by the War Department It is now divided into a medical corps, medical reserve corps and hospital corps all commanded by a chief surgeon who is subordinate only to the commander in chief of the National Guard The medical corps consists of medical officers commissioned after examination by a board consisting of not less than three medical officers of the National Guard The Medical Reserve Corps is to consist of duly qualified practitioners recommended by the chief surgeon

MARYLAND

Baltimore

Personal—Dr J A. F Pfeiffer has returned from Europe ——Dr A D McConachie has resigned from the faculty of the Maryland Medical College

School for Defectives Established—With the approval of the school board and the cooperation of Dr Adolf Meyer, head of the Phipps psychiatric clinic a class for children of defective mentality will be established at one of the public schools

Home for Invalid Children Opened—The Harriett Lane Johnson Home for Invalid Children was opened November 22 The principal address was made by Dr L Emmett Holt New York City, and Drs Abraham Jacobi and William H Welch Baltimore, also spoke

Bazaar for Widows and Orphans—The bazaar for the benefit of the Home for Widows and Orphans of Physicians was held in the Howard Street Armory, November 21 25 Mrs Eugene F Cordell was in charge and a number of the wives and daughters of Maryland physicians assisted The management hopes that enough money will be realized to pay off the balance of the indebtedness on the building, and also to secure a substantial sum for the maintenance of this home, the only one of its kind in existence

MICHIGAN

New Officers—Grand Traverse Leelanau County Medical Society, at Traverse City, November 4 president Dr F Holdsworth, secretary treasurer, Dr James V J Hall, both of Traverse City ——Tuscola County Medical Society at Caro, October 14 president, Dr J H MacKenzie, Reese secretary treasurer, Dr W C Carvin, Millington (reelected) ——Pontiac Medical Society at Pontiac, October 15 president Dr C W Mack, secretary, Dr I A Farnham ——Michigan State Association for the Prevention and Relief of Tuberculosis at Ann Arbor, November 1 president, Dr Herman Ostrander Kalamazoo treasurer, Dr H J Hartz Detroit ——Lenawee County Antituberculosis Society, at Adrian president Dr A W Chase, secretary treasurer, Dr I sh Morden both of Adrian ——Twin City Physicians' Club (Hancock and Houghton) at Hancock November 11 president Dr J C Turner, Houghton, secretary Dr M D Roberts Hancock ——Tri County Medical Society at Cadillac, November 7 president, Dr S C Moore, secretary treasurer, Dr Rudolph J F Odlan, both of Cadillac.

Personal—Dr O M Vaughan, Covert, has been unanimously elected president of the board of superintendents of the poor for Van Buren County, for a sixth three year term ——Dr H S Kiskadden, Detroit, fractured his arm in a machinery accident, October 23, and was operated on in Grace Hospital, Detroit, five days later ——Dr I Lindgren, Ishpeming, has started for his old home in Helsingfors, Finland ——Dr W H Price, Detroit, was elected second vice president of the National Milk Inspectors' Association at its annual meeting in Milwaukee last month ——Dr S Szudrawski, Manistee, has been appointed state medical inspector for the northern half of the ninth congressional district ——Dr Charles W Thompson, assistant superintendent of the Newberry State Hospital, has resigned ——Dr Glenn W Stockwell has succeeded Dr Benjamin P Brodie as surgeon of the Detroit Fire Department ——Dr G B Hoops Detroit, underwent an operation for appendicitis in Grace Hospital, recently ——Dr Joseph E Bennett, Wayne, while hunting in the Upper Peninsula, November 10, was accidentally shot fracturing his right femur just above the knee ——Dr James B Bradley, Eaton Rapids, has resigned as a member of the Prison Pardon Board to take effect January 1 ——Dr H. T Setheny, Menominee, was operated on in St Joseph's Hospital in that city, for the removal of gall stones, November 11

MISSISSIPPI

New Officers—Tate County Medical Society at Arkabutla, October 2 president, Dr H L Murphy, Arkabutla, secretary, Dr J S Eason, Coldwater

Personal.—Dr J Sidney Sharp, Grenada, has been appointed a member of the State Board of Health, vice Dr J C Armstrong, Water Valley, resigned ——Dr R M Saddler, Okolona, who had a cerebral hemorrhage several weeks ago, is reported to be improved, and has resumed practice ——Dr H N Stephen, Biloxi has accepted a position as surgeon on steamers sailing from New Orleans to the tropics ——Dr David A Spear has returned from abroad and has settled in Greenville ——The Newton Sanatorium, which was bought two years ago by Dr J T B Berry has been sold to Drs I W Cooper and W G Gill ——Dr J E Wallace, Biloxi, who has been ill with influenza has recovered and resumed practice ——Dr J A Rowan, Wesson, suffered a cerebral hemorrhage, November 2

MISSOURI

Personal—Dr W C Guss, Hannibal, who has been ill with pneumonia, has started for Florida ——Dr H G Dallas, Fulton, fractured his left leg in an automobile accident near Fulton, November 13, and Dr Dennis E Singleton sustained a strain of the back in the same accident ——Dr John E Bruere, formerly of St Charles, is reported to be seriously ill in New York City ——Dr Max Goldman, Kansas City, was attacked in his office by a patient, November 9, but succeeded in overpowering his assailant

Operations on Physicians—Dr James R Mudd, formerly of St Charles, who was operated on October 26 in the Deaconess Hospital St Louis is reported to be convalescent —— Dr John Bryant Independence was operated on in Johns Hopkins Hospital Baltimore recently ——Dr George P Pipkin, formerly superintendent of the Kansas City General Hospital, underwent operation for appendicitis, October 9 ——Dr Solomon Steward, Trenton was recently operated on and is reported to be making a good recovery ——Dr A I Nichols Ashland, was operated on in Columbus, recently, for a tumor of the right arm

St Louis

Personal—Dr Samuel T Nicholson has been appointed superintendent of the Sydenham Municipal Hospital for Infectious Diseases, Baltimore, vice Dr Joseph A Wright, resigned ——Dr John B Shapleigh has resigned as a member of the Hospital Board ——Dr Le Grande Atwood celebrated his eightieth birthday anniversary, October 16 ——Dr R. B H. Gradwohl has returned from Europe

Hospital News—The new building of the St Louis Maternity Hospital was dedicated with formal ceremonies, October 29 ——The country branch of the St Louis Children's Free Hospital will be established this month at Ridge Farm The institution will occupy temporarily the three buildings now used by the Grand Leader Country Club, and it is expected that next year a fireproof hospital building will be erected.

Visiting Staff Selected.—The hospital board has appointed the following visiting staff for the City Hospital and other institutions under its jurisdiction Of these, forty five are reappointments of old members of the staff medical division, O H Campbell, L S Luton, George C Crandall, L J Wilfort, C J Luyties, P George Richter, C H Neilson, H J Cummings, O H Brown, William Engelbach, Llewellyn Sale, John C Salter, W P Elmer and Edward H Eyermann, surgical division, A C Leggat, Willis Young, Ernst Jonas, Max W Myer, Francis Reder, Frederick Bailey, M G Seelig, E A Babler, William E Leighton, Louis Rassieur, O H Elbrecht, Robert E Schlueter and W C G Kirchner, former superintendent of the City Hospital, gynecologic and obstetric division, A N Curtis, George Gellhorn, Hugo Ehrenfest, P H Swahlen and F J Taussig, observation and neurologic division, C G Chaddock, M W Hoge, H Unterberg, W W Graves, S I Schwab and Percy J Farmer, genito urinary division, C E Burford, W M Robertson, H J Scherck H G Lund and J W Marchildon, eye division, J E Jennings, Ernst Saxl Meyer Wiener, Max Jacobs and A Collasowitz, ear, nose and throat division, W D Black, C F Pfingsten R Ph Scholz, H W Loeb and W M C Bryan, pediatric division, G Lippmann, Julius Rotteck, J R Clemens and T L Rives, orthopedic division, Alexander E Horwitz and Scott Parsons, dermatologic division, W H Mook, Joseph Grindon and J J Houwink, dental division, J P Harper, Virgil Loeb and William Oliver Appel

NEW YORK

Memorial Hospital Opened—The new Higgins Memorial Hospital, Olean, erected in memory of the late Gov Frank Wayland Higgins, by his sister at a cost of $50,000, was formally dedicated November 1

Academy Delegation Calls on Old Member—Dr Alfred Mercer *dean of the medical profession of Syracuse, received the* congratulations and good wishes of a delegation representing the Syracuse Academy of Medicine, November 14, on the occasion of his ninety second birthday anniversary

W Johnson, Hudson ——Niagara County Medical Society in Lockport, November 12 president, Dr Carl G Leo Wolf, Niagara Falls, secretary, Dr L R Hulbert, Lockport

No Tuberculosis Hospital for Yorktown.—The State Commissioner of Health has denied the application of the Westchester county board of supervisors for a tuberculosis hospital at Yorktown The refusal to grant the application was based on the objection of the New York City authorities on the ground that the establishment of such an institution would be a source of possible contamination to the water supply of the city

Personal—Dr Robert B Hammond White Plains, has been appointed a commissioner in lunacy ——Dr L M Andrews Warsaw, has been appointed physician to the Wyoming County jail ——Dr J Glenn Ernest, Lockport, has been elected coroner of Niagara County ——Dr Lucien Howe has been elected secretary and Drs Roswell Park and John B Coakley have been reelected trustees of the Buffalo Eye and Ear Infirmary —— Dr H B Pritchard, Syracuse, was caught between two automobiles and painfully injured, November 6

State Supervision of Dairies—A bill has been prepared for presentation at the approaching session of the legislature which will make the supervision of the milk supply at the dairy obligatory on the state instead of on the city as at present The New York Milk Committee which has prepared the bill believes that the licensing and inspection of dairies creameries and milk shipping stations should be done by the State Board of Health and that the State Department of Agriculture should control the health of dairy cattle and the sanitary conditions of the barns, etc , and the methods of milk production, while the city health department should test and inspect the milk when received

New York City

New Officers—New York Academy of Medicine, November 7 president, Dr William M Polk, secretary, Dr C F Adams

Personal—Dr Bernard Samuels has returned from Europe. ——Dr Lewis S Pilcher, Brooklyn, has been elected commander of U S Grant Post, G A R

Receipts for Hospitals—The treasurer of the Hospital Saturday and Sunday Association reported on November 12 that *the total collections for the year amounted to* $110,940

Small Pox on Steamer—The steamer *Barbarossa,* which arrived from Bremen, November 14, was detained at quarantine on account of a case of small pox among the passengers

Physicians in Realty Deal—A New York corporation said to be composed of one hundred physicians has purchased a farm of seventy acres known as Summit View near Armonk for about $30,000

Jewish Consumptive's Relief Society—The eighth annual meeting of this association was held November 15 to 19 Dr Abraham Jacobi delivered the principal address at the evening session of November 15 The society has a membership of 25,000 and more than 200 delegates were present at the convention

Millions Needed for Health Work.—Dr Joseph J O'Connell, health officer for the Port of New York, announces that he will apply for an appropriation of $2,000,000 from the legislature to improve the port quarantine facilities, for the enlargement of Swinburne Island and the erection of additional buildings which will be rendered necessary by the opening of the Panama Canal

Hospital Notes—Foundation plans have been filed for the construction of a six story hospital for the Volunteers of America to be erected on the corner of Beekman and Water Streets It will be known as the Volunteer Hospital and will cost $60,000 ——Designs have been approved for a six story structure to be erected at 41 43 East One Hundred and Twenty Third Street as an annex to the Hospital for Deformities and Joint Diseases

Membership of the County Society—A letter recently sent out by the Medical Society of the county of New York states that the society has a membership of 2,476 and that there are 2,083 physicians in the county who are not members Of these at least 2,000 are eligible for membership The letter sets forth the benefits to be derived from membership in the county society and urges each member to do his utmost to recruit at least one new member

Lecture Course for Nurses—The Department of Health, in cooperation with the Nurses' Settlement, Teacher's College and the Charity Organization Society, has arranged for a series of lectures to be given by its officers and representatives of the above organizations on the activities and methods of the city in dealing with public health matters, home nursing, social service work and charitable aid Various divisions of the department will be presented each week

Anniversary Meeting—The New York Academy of Medicine held its anniversary meeting and reception November 21, on which occasion Dr Charles Dana and Dr Algernon T Bristow, Brooklyn, read papers on "The Doctor's Future" Dr Abraham Jacobi, in a short address, made a plea for the general practitioner, and expressed the hope that the general practitioner would be retained 'modified in a sense, but still a general practitioner, and the friend and confidant of his patients"

New Hospital for Harlem.—Plans for a new building for the Hospital for the Treatment of Deformities of the Bones and Joints have been filed and the construction will soon be begun The equipment that has been planned will be much more elaborate than that of any other institution for the treatment of similar conditions in the country A rather unique feature will be a factory in the basement for the manufacture of shoes and surgical instruments

Fight Against Poisonous Matches.—The Municipal Explosives Commission, which after a long fight secured the adoption of a city ordinance forbidding the use of phosphorus and 'after glow" matches after Jan 1, 1913, find that they must begin their fight over in order to prevent the so called 'match trust" from putting into effect some plan by which they will be enabled to continue the sale of these matches for two years or until the federal law forbidding the manufacture and sale of phosphorus matches goes into effect on Jan 1, 1915

New Hospital Association.—The delegates of twenty nine hospital dispensaries met recently at the New York Academy of Medicine and organized an association to be known as the Associated Out Patient Clinics of the City of New York The aims of the association are to coordinate the work of existing dispensaries and out patient clinics to eliminate unworthy applicants for treatment, to promote proper standards of treatment, economy and efficiency in dispensary management Efforts will be made to limit the work of each dispensary to the district in which it is located

Campaign Against Cocain Sellers Progressing—The results of the efforts to prevent the illegal sale of cocain made in Brooklyn during the past three months have just been placed before the grand jury of Kings County The report shows that there have been fifty four indictments of alleged sellers of cocain by the October grand jury, making a new high record in the prosecution of this particular felony The revelations as to the extent of the use of this drug were amazing It was shown that pedlers on street corners, who were ostensibly selling pencils and other small wares, were using these as a blind while they were in reality selling cocain The sections where this drug was most freely sold were upper Fulton Street and lower Tompkins Avenue

New York Prepared for Cholera—It is stated by Dr Joseph O Connell health officer of the port, that quarantine regulations and examinations of vessels which come from the Mediterranean, Hellenic or Levantine ports are to be much more rigorous in consequence of the reported outbreak of cholera in the Turkish army Improvements have been in progress for the past eight months with just such a contingency in view and equipment and accommodations have been so increased that passengers that may have to be removed from incoming vessels may be cared for without difficulty and without the danger which attended the last visitation of cholera to this port Dr O Connell expresses the belief that it is typhus fever rather than cholera that we should fear, as typhus is more likely to be brought in by carriers and because less is known about this disease than about cholera

NORTH DAKOTA

New Hospitals—A new hospital is to be erected at Jamestown to be known as the Parkview Hospital and Sanitarium Dr W A Gerrish *is one of the incorporators* ——The Dunseith Sanatorium for tuberculosis, recently completed, is in charge of Dr James P Widemeyer, Rolla

Personal—The offices of Drs W P Baldwin and H J Rowe, Casselton, were destroyed by fire, October 24 ——Dr K H Beach, Dickinson, has been appointed superintendent and chief surgeon of the new Northern Pacific Hospital, Glendive, Mont, and will assume his new duties about January 1 ——Dr John G Arenberg, Grand Forks, has returned from Europe ——By a fire in Mohall, November 16, Dr J Halliday lost his office, fixtures and furniture

PENNSYLVANIA

New Officers—Bucks County Medical Society at Doylestown, November 13 president, Dr Walter H. Brown, Richlandtown, secretary treasurer, Dr Anthony F Myers, Blooming Glen (reelected)

Portrait Presented—At the meeting of the Berks County Medical Society at Reading, November 12, an oil painting of the late Dr Peter G Pertolett was presented to the society by Dr Samuel L Kurtz

Hospital Items—The Wilkes Barre City Hospital Association has purchased a lot on which it will erect a three story building, adjacent to the present building ——October 29 and 30 were harvest home days at the Mid Valley Hospital, Scranton at which gifts of vegetables, fruit, etc, were made to the hospital ——Chester County Hospital has purchased a tract of land north of the present location of the buildings at a cost of $1 500

Personal.—Dr Donald G Rafferty, Pittsburgh, is a patient in Mercer Hospital, suffering from malaria said to have been contracted while on an exploration tour in Abyssinia ——Dr H E Williams, West Coatesville sustained painful injuries in a fall November 17 ——Dr H F Smith, Scranton, has been appointed first lieutenant, M C, N G Pa, and assigned to the Thirteenth Infantry, vice Dr F F Arndt, resigned ——Dr Davis A Hogue, Altoona, who has been seriously ill with septicemia is reported to be improving ——Dr George W Wagoner, Johnstown, has been elected secretary of the Board of Managers of the Conemaugh Valley Memorial Hospital ——Dr E W Smitheman, Oil City is reported to be critically ill at the home of his father in Haddonfield, N J ——Dr K H Van Normán, house surgeon at the Pittsburgh Tuberculosis Hospital, has been elected assistant superintendent of the Johns Hopkins Hospital, Baltimore ——Dr John W Luther has been elected first burgess of the new borough of Palmerton

Philadelphia

New Officers—Aid Association of the Philadelphia County Medical Society, November 11 president, Dr Roland G Curtin secretary, Dr Lewis H Adler, Jr

Personal—Dr John J Gilbride has been appointed lecturer in surgery in the Medico Chirurgical College of Philadelphia ——Dr Eva Rowley Frankford has been appointed pathologist on the staff of the Kalamazoo (Mich) State Hospital.

Hospital News—The managers of the Children's Hospital have decided to erect a group of buildings on a new site having double the capacity o [illegible] ent institution, [illegible] be provided with the [illegible] upment for [illegible] of children and the [illegible] on Eighteenth ground covering more than one and one half acres One of the managers of the hospital has given $100,000 for the purchase of the site

Money for Hospital in China.—Dr Josiah C McCracken, head of the medical school in Canton, China, established by the University of Pennsylvania Christian Association, has come to Philadelphia to raise $85,000 for the erection of a hospital in connection with the school One wing, 77 feet in length, was recently completed at a cost of $17,000 and is now being used to its fullest capacity It is proposed to add 112 feet to this wing and in addition, to build a central section which will contain executive offices, laboratories, private wards and operating room

Appropriation for Home for Indigents—On November 7, Councils Finance Committee recommended an appropriation of $10,000 for a temporary home for the female indigent on the Alexander Brown property, in Torresdale, the tract once selected for a permanent home for the poor Councils passed a bill providing for the reorganization of the divisions of house drainage and nuisances under one inspector to be known as the chief sanitary inspector Mayor Blankenburg recommended to Councils a creation of the position for superintendent of Byberry Farms for the insane at a salary of $4,000 a year Director Neff stated that a physician is now needed there to take charge of the insane patients

The Rush Society—This society, established through the initiative of the Medical Department of the University of Pennsylvania, was organized November 2 Its objects are similar to those of the Harvey Society of New York, namely the diffusion, by lectures, of knowledge concerning recent advances in medical and the biologic sciences and public hygiene Dr Richard M Pearce was elected president, Dr Alfred Stengel, vice president, and Dr William Pepper, secretary treasurer It proposes to present during each academic year from six to eight lectures, the first to be given in January Arrangements have already been made for lectures by Dr Theodore C Janeway Columbia University, New York City, and Dr M J Rosenau of Harvard

TEXAS

New Quarantine Station Planned—An additional building has been authorized for the United States Quarantine Station Group, Bolivar Roads, Galveston

New Officers—Fourth District Medical Society at Brownwood, October 21 22 president, Dr T K Proctor, San Angelo secretary, Dr J M. Horn, Brownwood Lampasas was selected as the next place of meeting——Nacogdoches County Medical Association organized at Nacogdoches, October 9 president Dr J H Barham, secretary, Dr T J Blackwell, both of Nacogdoches

Raising of Quarantines Delayed.—After conference with State Quarantine Officer Dr I L McGlasson, Galveston, and Dr Ralph Steiner president of the State Board of Health in Austin, October 30, it was decided that, on account of the prevalence of yellow fever in Mexico and South American countries the maritime quarantine, which has ordinarily been raised November 1, should be continued for at least thirty days after that time

Personal—The office of Dr Adam M Autrey, Houston, was seriously damaged by fire October 27——A board of health has been organized in Corpus Christi consisting of Drs T J Turpin, E O Arnold Herbert Caldwell, W E Carruth and Sherman T Dodge, with Dr P D Spohn acting city physician and Dr Roy Miller, sanitary commissioner as ex officio members——Dr Herbert E Stevenson El Paso, has been elected president of the local branch of the American National Red Cross——Dr M J Bliem has been elected president and Dr M L. Burnham vice president of the San Antonio Society of Social Hygiene.——The residence of Dr P H Chilton Comanche was burned to the ground October 5——Dr R. M Prather Beeville, who has been ill with septicemia, has recovered——Dr R W Knox, Houston, has returned from Europe ——Dr George T Baskett, San Angelo, has been appointed superintendent of the St Peter (Minn) State Hospital

GENERAL

Annual Conference on Labor Laws—The sixth annual meeting of the American Association for Labor Legislation will be held in Boston December 27 28 Among the topics to receive attention in the discussions are "protection against lead poisoning' and "occupational diseases"

New Hospital in Colombia.—The United Fruit Company is building a hospital at Santa Marta, Colombia South America at a cost of $100 000 The building will be one of the finest in Spanish America and will have a research department affiliated with the medical department of Tulane University, New Orleans

Alburger, Indianapolis, vice presidents, Drs A D Willmoth, Louisville, E O Smith, Cincinnati, and G M Young, Evansville, and secretary treasurer Dr Benjamin L W Floyd, Evansville (reelected) The next meeting will be held in Evansville, in November, 1913

Railway Surgeons Elect—The New York and New England Association of Railway Surgeons held its twenty second annual session November 13, and elected the following officers president, Dr John W Le Seur, Batavia, N Y , vice presidents, Drs C A Pease, Burlington, Vt , and Dr William H Marcy Buffalo, N Y , corresponding secretary, Dr George Chaffee, Brooklyn, recording secretary, Dr J H Reid, Troy, N Y , treasurer, Dr J K Stockwell, Oswego, N Y

Annual Meeting of Tri-State Society—The nineteenth annual meeting of the Tri State Medical Society of Arkansas, Texas and Louisiana, was held in Shreveport, November 12 13 Texarkana was selected as the next place of meeting, and the following officers were elected president, Dr T B Younger, Fisher, La , vice presidents, for Louisiana, Dr John L Scales Shreveport, for Texas, Dr William G Hartt, Marshall, and for Arkansas, Dr George P Sanders, McNeil, secretary treasurer, Dr Jacob M Bodenheimer, Shreveport, La (reelected)

Medical Milk Commission Report—The Medical Milk Commission of Essex County, N J , has issued for distribution among physicians a pamphlet containing the twenty third report of the commission including the forms of certificates made by the chemist, the bacteriologist, the visiting physician, the veterinary surgeon, the visiting committee and other committees of the milk commission, an abstract from the by laws, the medical milk commission laws of New Jersey, a copy of the agreement between the milk commission and the producer of certified milk, and an abstract from the annual report of the State Board of Health of New Jersey, setting forth the effective manner in which an epidemic of scarlet fever was prevented by the prompt handling of some suspected cases that occurred among the employees of a certified milk dairy The report affords information of value to other medical milk commissions, as it is the actual working record of an efficiently conducted certified milk commission

Bequests and Donations.—The following bequests and donations have been announced

Children s Hospital Free Home for Consumptives, Perkins Institution for the Blind Boston Floating Hospital and Kindergarten for the Blind each one ninth of the estate of Charles John Prince Boston on the death of his wife

Presbyterian Hospital Chicago Visiting Nurses Association, each $5 000 Chicago Home for Incurables and Home for Destitute Crippled Children each $10 000 by the will of Miss May Buckingham

St Joseph s Hospital, Philadelphia, $12 500 by the will of Isabella McLinden

St. Mary's Free Hospital for Children, New York City Presbyterian Hospital Charity Organization Society New York Association for Improving the Condition of the Poor and Children's Aid Society each $10 000, by the will of William Hall Penfold

S R Smith Infirmary Thompkinsville, Staten Island the fund of $108 333 as the result of a campaign to raise $100 000 which was inaugurated October 18

Johns Hopkins Hospital Baltimore $200 000 the gift of James Buckingham Brady New York City for the erection of a six story building to be known as the James Buckingham Brady Institute containing laboratories and public wards for the study of urology in addition $15 000 annually for maintenance and a substantial sum by will Dr Hugh H Young is to have charge

The Journal of Pharmacology and Experimental Therapeutics—Within the brief period since its establishment about three years ago, the *Journal of Pharmacology and Experimental Therapeutics*, under the editorship of Prof John J Abel of the Johns Hopkins Medical School, has won a prominent place for itself among the publications which aim to present original contributions to the medical sciences Pharmacology pursued as a distinctive branch of study and encouraged as a field for research has a comparatively recent history in the United States The formation of a thriving society of active pharmacologic experimentalists and the launching of a new journal devoted exclusively to this field, all within recent years, give an indication of the interest which has been aroused in the rational study of the action of drugs and their therapeutic applications Few changes have come so rapidly in the evolution of medical studies in this country as has the transformation of the old materia medica of preceding generations into the scientific pharmacology of to day With the beginning of Volume 4, September, 1912, Prof Arthur R Cushny, the well known pharmacologist of University College, London, formerly at the University of Michigan, has become joint editor with his American colleague, Professor Abel At the same time Sir T Lauder Brunton, Dr H H Dale and Dr F Ransom of London, Sir Thomas Fraser of Edinburgh, Prof J T Cash of Aberdeen, Prof R Stockman of Glasgow, Prof J N Langley and W E Dixon of Cambridge, Prof C R. Marshall of the University of St Andrews and Dr J A. Gunn of Oxford joined the board of associate editors, which already includes the names of many of our foremost American workers in this field This new arrangement in the direction of editorial expansion on both sides of the Atlantic is likely to attract the best pharmacologic contributions of English speaking countries It cannot fail to enhance the prestige of the *Journal*, which already has a creditable record, and the science which it represents will reap the benefit that accrues from a forceful and critical medium of publication This felicitous cooperation of the ablest of British and American colleagues in the management of a scientific project betrays the spirit of the times It exemplifies the truly international character of work in science and medicine, in which the boundaries of states have become obliterated The new venture calls for a word of congratulation and deserves hearty support

THE SCHRANK CASE

The case of the would be assassin of Mr Roosevelt, John Schrank, was disposed of November 23 by the Municipal Court of Milwaukee County

We present below the summary and conclusions of the five alienists appointed by Municipal Judge A C Backus, as commissioners to examine Schrank and determine his mental state The questions on which the commissioners were instructed to report were 1 Is the defendant at the *present time* insane? 2 Is the defendant in such condition of mind that he is able to advise with counsel and conduct his defense?

It will be remembered that Schrank, when arrested, expressed the belief that Colonel Roosevelt had guilty knowledge of President McKinley's death and that "*a man who wanted a third term had no right to live*" His examination developed the fact that a whole body of systematized delusions had grown up in his mind about "sacred traditions" that must be defended with life if need be, and that Colonel Roosevelt, like Caesar, was ambitious and deserving of Caesar's fate

The summary and conclusions of the commissioners are as follows

Summary—'We have limited the scope of our investigation and inquiry to the questions we have been asked to determine and summarize briefly John Schrank, aged 36 years single, bar keeper and saloon keeper, and of limited educational opportunities, with insane heredity, was born in Bavaria, March 5 1876, and came to this country twelve years later Apparently he developed normally, but early in life showed a particular fondness for the study of the histories of this and other countries, and also for the composition of poetry In the course of his studies of history, and especially of the Constitution of the United States and of Washington's Farewell Address, he developed the belief that this republic is based on the foundation of four unwritten laws to which he also refers as the 'Four Sacred Traditions

'In 1901 he had a very vivid dream, which at that time he recognized as only a dream [of seeing McKinley in his coffin point to a person as his slayer who wore the aspect of Roosevelt] the memory of which has frequently recurred to him ever since In the course of the pre-convention campaign [in 1912] the belief that the four unwritten laws or the 'Four Sacred Traditions' are in danger comes to him, and later on the nomination of a presidential candidate by the Progressive Party, he begins to attach particular significance to the dream he had in 1901 He meditates deeply on this and, in the course of a few weeks, there appears to him a 'vision' accompanied by a voice which, in effect, commands the killing of the man through whose acts and machinations he believes the sacred traditions to be endangered, and who he also believes is, through a conspiracy, concerned in the assassination of a former president He continues to ponder on the subjects set forth awaiting the appearance of a person who would carry out the act suggested by the vision, but shortly arrives at the conclusion that he, and not someone else, is the chosen instrument He at once sets forth to accomplish his mission, following his victim until he finally comes up with him

During his examination as to his sanity, he conducts himself in perfect accord with his beliefs, and expresses a regret at not having died at the hands of the mob if such a result would have proved of benefit to his chosen country

Conclusions "1 John Schrank is suffering from insane delusions grandiose in character, and of the systematized variety

2 In our opinion he is insane at the present time

"3 On account of the connection existing between his delusions and the act with which he stands charged, we are of the opinion that he is unable to confer intelligently with counsel or to conduct his defense

"Richard Dewey, M D, Chairman
"W F Becker, M D, "D W Harrington, M D,
'Frank Studley, M D, 'William F Wegge, M.D,
'Commissioners"

In accordance with the finding of the commission, Judge Backus has ordered the commitment of Schrank to the Northern State Hospital for the Insane, near Oshkosh, Wis, and he was taken to the institution November 25

The noteworthy feature of these proceedings is the appointment of experts solely for the purpose of advising the court without reference either to prosecution or defense, thus avoiding the 'battle of experts' which rightly or wrongly often brings discredit on psychiatry

LONDON LETTER

(From Our Regular Correspondent)

London, Nov 16, 1912

The National Insurance Act Probable Rejection of the Government's Terms

The resolutions passed by the various divisions of the British Medical Association are so far, in the great majority of cases, in favor of rejecting the government's amended terms, which, as stated in my previous letter, are a considerable advance, as regards remuneration, on those previously offered, but do not grant many of the "six points" formulated by the association Perhaps the point on which the profession is most hostile is the failure to insert in the act the income limit of $10 a week for insured persons eligible for medical benefit The feeling is that contract practice is semi charitable and should be confined to persons in poor circumstances In the past it has been possible to take contract work at low rates because those a little higher in the social scale could be attended at moderate fees, which, though moderate enable the physician to pay his way In the act, the income limit is $15 a week for all persons except those who are manual workers, for whom there is no limit whatever A mechanic earning as much as $40 a week (it must be remembered that this sum would represent nearly twice the same wages in this country as in the United States in consequence of the cheaper cost of living) is compelled to insure and can demand 'free medical attendance, drugs and appliances" Moreover any person who has been insured for five years may continue as a voluntary insurer after he rises in the world and passes the income limit Thus, if he becomes an employer and a rich man instead of paying the fees of his station in life h can continue to obtain medical attendance at the same rate as a workman Another condition which the profession resents is that disciplinary power is vested in the local insurance committees which contain a large number of representatives of the friendly societies It is held that like other learned professions such as the church and the law, the medical profession should be disciplined by itself

Criticism of the Regulations

The National Medical Union, an association of northern physicians formed at Manchester to strengthen the resistance of the British Medical Association to the act, has issued a pamphlet strongly criticizing the act It is declared that private practice among the poorer classes will be undermined At every turn there will be bureaucratic interference The varying forms to be filled up, the official accounts to be rendered and the amount of gratuitous work to be performed will be among the minor fruits of the system Members of the profession should never agree to having their lives harassed by the institution described as the "complaints committee" The root fault of the whole scheme is the statutory obligation to attend which is placed on the physician Medicine is a delicate and personal art and the relation between patient and physician is best left to the parties concerned The disciplinary regulations would destroy the old relation based on freedom, confidence and respect and substitute for it a legal obligation

The State Medical Service Association

The first general meeting of the State Medical Service Association which was formed in Liverpool in July, has just been held in London, with Professor Benjamin Moore in the chair One hundred and thirty five physicians and a few laymen have, in response to circulars explaining the objects of the association, become members An executive committee was appointed with Dr G A Heron as chairman, and arrangements have been made for the formation of district branches Negotiations for the issue of a weekly journal, the *Medical World*, have been completed The association has nothing to do with the controversy arising out of the national insurance act The conception of the association and the scheme as advocated preceded the introduction of Mr Lloyd George's scheme into the House of Commons The association contends that the interests of the public health in this country demand a state-supported medical service, which should unite preventive and curative medicine and be available for every man, woman and child, rich or poor Another object is the nationalization of hospitals It is proposed that these institutions should be used for consultative, operative and therapeutic work at the request of and in association with the patients' own physicians The scheme provides that the whole service shall be administered by a board of health, under a minister of public health, with cabinet rank, assisted by expert medical advisers The association holds that in existing circumstances many of the most able and willing researchers are compelled by economic conditions to desert the centers of investigation in order to earn a living in practice and vast stores of the most useful material are neglected, because in the struggle to obtain a livelihood the busy general practitioners have no time to utilize it The evils at present due to long hours and irregularities of work, the unavoidable waste of time in the building up of practices, and the financial dependence of the practitioner on the patient, can, in the association's view be remedied only by the organization of the profession as a branch of the nation's civil service The time has come it is held when every medical practitioner, man or woman, should be guaranteed an adequate and certain salary during the active years of service, coupled with a system of gradual promotion, and followed by a generous pension However fascinating this scheme is not likely to receive much support in the profession outside a small minority holding socialistic or "advanced" political views

Alcohol and Cancer

Delivering the annual lecture under the Lees Roper Trust at Norwich recently, Sir Alfred Pearce Gould K C V O, said the experience of the United Kingdom Temperance and General Provident Institution was that death from cancer was more than twice as frequent among the non abstaining section of their policy holders as it was among the abstaining section It had also been shown that the cancer incidence in men of different occupations varied directly with the habits as regarded alcohol of those engaged in such occupations For example cancer was twice as frequent among brewers and London publicans as among clergymen His experience of this disease enabled him to say that it was more rapid and more distressing among those who took alcohol and that free consumption of alcohol added greatly to the rapidity and severity of the disease The taking of alcohol was not the cause of cancer but it certainly lessened a man's power of resisting the attack of the disease

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Nov 8, 1912.

Hematogenic Origin of Certain Forms of Acute Appendicitis

Notwithstanding clinical, anatomic, pathologic and experimental investigations tending to show the hematogenic origin of certain forms of appendicitis, this has not been unmistakably demonstrated until now, for in no case has it been possible to prove through blood culture the preliminary circulation in the blood of the germs which produced the lesion in the appendix The report which Professor Widal made at the meeting of the Académie de médecine, October 22, has the value of experimental evidence In a woman who for two weeks had presented the classical picture of a typhoid infection without any symptoms of appendicitis, blood-culture permitted the isolation twice of the *Bacillus paratyphosus B* At the end of two weeks, symptoms of peritonitis developed, and were followed by death in twenty four hours Autopsy revealed the presence of a perforating appendicitis accompanied by ecchymotic lesions of the cecum The paratyphosus B bacilli existed in almost a pure state in all these lesions Histologic examinations confirmed the finding of invasion of the appendicular and cecal walls through the blood and showed the presence in the capillaries of numerous colonies of eberthiform bacilli This typhlo appendicitis presented the only intestinal sign of septicemia The small intestine was entirely normal, there was not the slightest lesion of Peyer's glands or of the lymphoid organs This observation makes clear how appendicitis can develop after any one of several general infections or even after a subcutaneous suppuration

First International Congress of Pediatrics

This congress, organized by the Association internationale de pédiatrie, was held in Paris, October 6 10 Unfortunately it did not have a full measure of success owing to the absence of American and British physicians, then, too the manner of recruiting members of the association lays itself open to criticism In his opening address Professor Hutinel of Paris, president of the congress, said that this body should be composed only of physicians and surgeons devoted especially or exclusively to the study of pediatrics, such as those who direct infant hospitals, infant asylums or infant dispensaries and especially teachers of pediatrics "The number of the members of our association," said Hutinel "has been largely reduced in this way, nevertheless I believe that it ought to be reduced still further It is our desire that our meetings should have a scientific interest and a true scientific importance and that the association should be composed only of the leaders in our specialty" It is to be inferred that admission to the association is closed to practitioners who do not have a hospital service and this is to be regretted, for among these practitioners there are some who have won a just reputation by their work in pediatrics Of subjects discussed, poliomyelitis would evidently have gained if Americans had come and reported the results of their experiences to the congress As this subject was discussed at the recent International Congress on Hygiene and Demography held at Washington (THE JOURNAL, Oct 5 p 1313), I shall not refer to it Among the reports on infantile anemias that of Professor Czerny of Strasburg deserves special mention

ANEMIA OF ALIMENTARY ORIGIN IN INFANTS

It is often customary to call all pale children anemic, but according to Czerny anemia should be distinguished carefully from mere paleness, the latter, of nervous origin is present in vasomotor troubles and is found in cases in which the blood is normal For diagnosis of anemia, it is necessary that the mucous membrane as well as the skin should be pale and that the blood examination should show a diminution in hemoglobin and in the number of the red cells Although paleness is often found among infants of all ages it is almost exclusively in the first year that anemia is observed After the second year it is relatively rare Insufficient feeding alone does not determine anemia, for anemia may accompany a diet that is apparently sufficient in quantity or which is even more than enough for the needs of the child It develops exclusively among certain children who have been fed on milk exclusively for a long time Anemia of alimentary origin comes on by degrees In some cases the paleness of the skin and of the mucous membranes and the change in the condition of the blood are the only symptoms of the disease, and in other cases there is also a hypertrophy of the spleen In these cases enlargement of the spleen comes first and anemia follows Czerny believes that cases of anemia with hypertrophy of the spleen are due to a combina tion of a predisposition toward anemia and the exudative diathesis or hereditary lymphatic temperament It is to be noted that anemia always develops at a time when the child is quite fat Czerny attaches particular importance to the symptoms of obesity, for experience shows that obesity can be developed only by a food rich in fat, such as milk generally is Children who for one reason or another do not tolerate milk well or who even refuse it and therefore are given a regimen in which carbohydrates predominate never become so fat as the others and never acquire alimentary anemia In addition to the obesity these children often show a softening and insufficient development of the muscles Anemia of alimentary origin is related only to an exclusive milk diet and therefore in treatment the regimen should be corrected At the beginning of the anemia and in light cases it will be sufficient to withdraw a third or a half of the milk ration and to fill out the regimen with cereals, oatmeal, rice, tapioca, etc, vegetables and fruit In severe cases it is necessary to exclude milk altogether or to reduce the quantity to from 100 to 200 gm a day at the most Czerny gives meat twice a day in addition to cereals such as oatmeal, rice and tapioca, and vegetables and fruit In changing the regimen in the manner described it is necessary to pay attention at the beginning to the digestion of the child, especially if diarrhea is present This must be cured before putting the child on a mixed diet Children who are constipated and whose stools are rich in lime soaps following an exclusive milk diet may safely change from one diet to the other This change will succeed better if only four meals a day are given By these means Czerny has been able to cure a severe case of anemia in three or four months

BERLIN LETTER

(From Our Regular Correspondent)

Berlin, Nov 9, 1912

A New Public Health Institution at Saarbrücken

A third institute for hygiene and infectious diseases has been erected at Saarbrücken similar to the institutions at Gelsenkirchen and Beuthen for the industrial districts of Rhenish Westphalia and Upper Silesia The building has twenty eight light, airy rooms for the different departments The task of the institution is the scientific treatment of all hygienic and bacteriologic questions, for instance, questions of hygiene in mines, smelters and factories, the supply of water and regulation of sewage, elimination of smoke, soot and dust, as well as the bacteriologic diagnosis and elimination of infectious diseases To the new institution are transferred the duties of the local institute for bacteriologic investigation for the elimination of typhoid, as well as the station for medical examinations and the Trier training school for the disinfection service —an amount of important work thus devolves on the director of the institute, Prof Dr Lentze, and on the department manager and four assistants

Legislation with Reference to Nursing Bottles

A bill for the regulation of nursing bottles will soon be presented to the Reichstag The bill reads 1 Children's nursing bottles with glass or rubber tube, and also parts of such bottles, must not be manufactured, kept in supply for sale, sold or otherwise brought into commerce, or imported from foreign countries 2 Whoever violates paragraph 1 shall be punished with a fine up to 150 marks (about $36), or with imprisonment In addition, the articles may be confiscated without regard to whether or not they belong to the convicted persons If the prosecution or conviction of certain persons is not practicable, the confiscation may be independent In the official preliminary statement stress is laid on the great mortality of children during the first year of life, which is still extraordinarily high in spite of the decrease that has been noticed in the last few years It is the general opinion of physicians that nursing bottles with glass or rubber tube are very likely the source of many infant deaths The tube bottles are popular with many people because the children may be left to themselves with these They are placed in bed and the children can suck at liberty while the mother goes about her work, whereas the bottle without a tube must be, as a rule, held in the hand by the nurse during the time of feeding Bottles with tubes are difficult to clean and to keep free from germs If they are left, as is generally the rule, to the children, there is danger on the one hand, of a lack of the regularity in feeding, so important in the nutrition of children, and on the other, danger of overfeeding According to information received from all parts of the kingdom there is no question but that sickness and death may be caused by these bottles Attention is especially directed, in addition to the frequent diseases of the digestive organs, to those of the mouth and laryngeal cavity, such as thrush aphthous and ulcerative processes of the oral mucous membrane, inspiration pneumonia, scrofula, over feeding, emaciation

Vienna, Nov 9, 1912

Wounds Caused by Rifle Bullets in the Balkan War

In a report to the medical society, Professor Tedlicka who is acting as Austrian Red Cross surgeon in Belgrade, stated the results of his experience with 670 wounded soldiers in the Turkish war raging in the Balkan peninsula He calls the modern small caliber bullet a very humane instrument the injuries from which are usually severe but heal rapidly The majority of shots affect the skull or some internal organs as the bullets usually penetrate the body Injuries of the lungs, liver, brain, abdomen and even penetrating heart wounds heal promptly Professor Tedlicka has had only two amputations among his cases and only twenty limbs required plaster of Paris bandages The modern bullet is aseptic, owing to the heat developed by the high power powder As it is carried along with enormous velocity it finds no difficulty in traversing four to six men one behind the other If long bones are struck they are shattered to pieces only if the bullet has lost much of its original momentum Shots through the femur, the humerus and the skull have been observed with healing of the wounds within a fortnight A large percentage of the injuries are caused by the bayonet, proving the frequency of hand to hand combat in this war An interesting feature of the injuries among the Turkish captive soldiers is the fracture of the base of the nose This injury is caused either by the recoil of the Mauser rifle or by the blowing into the face of the occluding lever of the rifle's magazine The soldiers have had no experience in the use of these weapons and therefore are slow to take any precaution against such an accident Professor Tedlicka was full of praise for the first aid pack carried by the Servian soldier, to which he ascribed a large share of the prompt healing of the wounds

Paleotti,[6] formaldehyd is distinctly antiseptic in the concentration of 1:50,000

We may therefore conclude that the chemical data are still too scanty to throw much light on the antiseptic action of hexamethylenamin in the tissues and secretions, but that they therefore do not preclude the possibility of this effect Unsatisfactory as this conclusion is—and it is to be hoped that deficiencies will soon be removed—at least it leaves the way open for the bacteriologic evidence

BACTERIOLOGIC PROOF OF THE EFFICIENCY OF HEXAMETHYLENAMIN

Bacteriologic evidence of the existence or concentration of a chemical substance cannot compare with satisfactory chemical proof, but in the absence of the latter, it deserves considerable confidence Indeed, the bacteriologic information is perhaps more directly applicable to clinical problems In the case of hexamethylenamin the bacteriologic data are much more concordant and definite than are the chemical

In the urine Jordan[1] found complete agreement with the chemical data giving 30 grains of the drug per day, he found putrefaction to be retarded slightly if the reaction was neutral or alkaline *very markedly retarded or completely prevented* if the reaction was acid

In the bile Crowe[7] found a marked bactericidal effect with a daily dosage of 5 gm (75 grains).

In the cerebrospinal fluid Crowe[8] found that the same dosage had a marked inhibitory effect on cultures

The results of Crowe have been generally accepted, and deserve to be accepted until they are contradicted by equally convincing bacteriologic or chemical evidence Burnam alone seems to doubt their validity but he fails to record any bacteriologic experiments His refutation appears to be based entirely on his chemical data which we have already discussed That hexamethylenamin may split off effective quantities of formaldehyd even in an alkaline medium is shown in the experiments of Sollmann in which it prevented the putrefaction of a pancreatic maceration in 1 per cent sodium carbonate It is possible that this is due to the binding of the alkali by the proteins[9]

EXPERIMENTAL THERAPY

This is also in favor of hexamethylenamin Flexner and Clark[10] showed that it has a positive, if limited prophylactic value in experimental poliomyelitis and a similar result is reported by Crowe for subdural injections of streptococcus cultures

CONCLUSIONS

From the preceding considerations the following conclusions represent the actual state of our knowledge

1 The antiseptic action of hexamethylenamin seems to be due solely to the liberation of formaldehyd

2 This is proportional to the concentration of the drug and therefore to the dose and in the urine at least inversely proportional to the quantity of urine

3 The liberation is most active in acid urines but it may occur to a limited extent even if the reaction is alkaline, not however, in the presence of free ammonia

4 Hexamethylenamin, after its administration, is present in all the tissues and secretions The chemical data as to its concentration, and as to the liberation of formaldehyd, are too scanty to be of much service, on the other hand, they do not justify the rejection of bacteriologic or clinical data

5 The bacteriologic results show that the administration of hexamethylenamin prevents the putrefaction of acid urines, that it has a much smaller effect on alkaline urines, and that it confers a marked bactericidal effect on bile, and a distinct but limited antiseptic effect on cerebrospinal fluid

---

[6] Quoted from Jordan (see Note 1)

[7] Crowe S J Arch internat pharmacodyn et thérap, 1908 xviii 315

[8] Crowe S J Bull Johns Hopkins Hosp 1909 xx. 102.

[9] This suggests that the administration of alkali (sodium acetate or citrate) would not interfere with the systemic action of hexamethylenamin while it would tend to prevent the urinary irritation Alkalies would of course be inadmissible if urinary antisepsis is desired

PEEKE'S EPILEPSY CURE

W H Peeke, 4 Cedar Street, New York, advertises and sells a "cure for fits" Peeke styles himself "Professor" and has the letters 'F.D"—whatever they may mean—after his name Those who answer Peeke's advertisements are sent a free bottle of his "infallible remedy" and a thirty two page pamphlet purporting to discuss epilepsy and its treatment Like all quacks, Peeke is particularly bitter against his competitors and especially against those who, he asserts, have copied his booklet Says Peeke "None of these rascally quacks possess intelligence sufficient to correctly compose ten words of a medical treatise" According to Peeke, the cause of epilepsy is "disharmony of the action of the double nervous system" A full size bottle of the cure is sold for three dollars Peeke claims that his remedy is "absolutely harmless" and that "the tender babe, the delicate woman, the sturdy vigorous man can alike take it"

A cursory examination of the nostrum was made in the Association's laboratory The chemists report

'The specimen was a brown solution having a salt like, bitter taste *and an alkaline reaction* Alcohol, *alkaloids and* iodids were absent Quantitative tests indicated the presence of bromin and ammonia equivalent to about 13.7 gm of sodium bromid and about 4.1 gm of ammonium bromid in each 100 c.c. of the preparation The residue on drying amounted to about 18.4 gm in each 100 c c Small amounts of an alkali probably sodium carbonate and of a bitter substance, probably gentian, were present"

The analysis shows that Peeke's Remedy, like practically every other fraudulent 'cure for fits," depends for its action on bromids Peeke's fraud does not even have the saving grace of novelty Even the lies he tells are old. The labels he sends out on his stuff contain the following statements

> A perfectly safe remedy
> Contains nothing whatever that will be injurious to either body or mind
> *It can be used with perfect safety by the youngest or oldest* suffere

A preparation of the bromids is not a "perfectly safe remedy" in the hands of uninstructed laymen, neither in such hands can the preparation 'be used with perfect safety," nor is it true that it 'contains nothing whatever that will be injurious to either body or mind" It would seem that the federal authorities have three counts on which to declare this fraud misbranded under the Food and Drugs Act

Correspondence

Diagnostic Misinformation at a Health Resort

To the Editor —Many and curious are the tales that are brought back to us by patients from their visits to *Kurorte* Even if the tendency of the laity to distort medical information be discounted, there must be a grain of truth in their version *of the diagnostic misinformation occasionally* meted out to them, armed with which they seek out the family physician and challenge him for his failure to make similar composite diagnoses

There are capable *Kurärzte*, of course, although it will be evident at a glance that the particular one in mind is not of this class

Concerning the experience that gives occasion to these remarks, let me explain A woman living in the central part of this state visited one of the well known and most widely advertised *Kurorte* in this country She did not consider herself ill, but wished to indulge in baths and general treatment *in lieu of spending a vacation period at a fashionable* summer resort She consulted the physician in charge and submitted to him, for examination a single specimen of urine taken from an unmeasured twenty four hour excretion The result of the analysis is shown

Can anything be more ludicrous or—must it be confessed—*more absolutely stupid?* Please note the *composite character*

Please Take this Report to the Doctor's Office for Explanation

of this urine it was ammoniacal, highly acid, contained a large amount of phosphates, brick dust sediment, no crystals and sodium and potassium urates!

The foregoing examination was made by the "analyst," who passed it along to the examiner for "remarks" These "remarks" are based on the urinalysis and are the comments of the physician in chief of the institution "Acute nephritis phosphaturia, scant elimination" As a matter of fact, this analysis does not contain a grain of evidence that any one of those three conditions existed Just what it does mean I leave to some cleverer translator of urinary findings than I

This patient was referred to me by her own physician, and my examination corroborated his in the positive exclusion of any existing abnormality, save the merest and occasional trace of albumin without further signs or symptoms of ill health

What comment need be made on the facts presented here? The ignorance shown by both the "analyst" and the physician in charge is deplorable in the extreme And when one considers the effect on the patient of such gross misinformation as to facts (in this particular instance charging a healthy person with suffering from an acute nephritis), the danger of permitting men of this caliber to assume positions of such responsibility is indeed apparent

Arthur J Patek, M D, Milwaukee, Wis

Glucose in Mince-Meat

To the Editor —In a recent number of *Good Housekeeping* Dr Wiley discusses the subject of mince meat One of the ingredients which Dr Wiley would allow in mince meat is "sugar," by which he means cane sugar An ingredient he would prohibit is glucose, or grape sugar Concerning the latter he makes the following statement "It is not a condiment, not a sweetener It needs to be sweetened itself No one can justly claim for it a higher nutritive property than an equal amount of sugar, many think it to be quite inferior"

What are the known and established facts? They are these 1 Glucose is a sweet tasting sugar, but is not so sweet as cane sugar 2 Glucose is produced as the end product of starch digestion in the gastro intestinal canal (dextrins being intermediary products) and as such is absorbed in large quantity into the blood and oxidized in the body 3 In the stomach and the intestine cane sugar is broken up into an equal mixture of glucose and levulose, both of which are absorbed by the blood, levulose, however, is largely converted by the liver into glucose so that the total effect of giving ne sugar is nearly the same as though glucose itself had been administered 4 Glucose is the normal sugar of the blood, being produced from protein when it is destroyed in the organism so that even in fasting the blood contains the normal content of 0 1 per cent of glucose 5 Starch is converted into glucose through water addition, in consequence, the heat producing power of 1 gm of glucose is somewhat less than 1 gm of starch Cane sugar is, in like manner, converted into levulose and dextrose through water addition, and therefore the heat producing power of 1 gm of cane sugar is about 5 per cent greater than of 1 gm of its products This is apparent from the following equation

Cane-sugar + water = glucose + levulose
1 molecule + 1 molecule = 1 molecule + 1 molecule
1 9 gm + 0 1 gm = 1 gm + 1 gm
7 518 calories + 0 0 calories = 3 730 calories + 3 720 calories

It is evident that 1 9 gm of cane sugar containing 7,518 calories unite with 0 1 gm of water, forming 2 gm of equal parts of glucose and levulose containing 7,468 calories The loss of 50 calories involved in the reaction amounts to 0 7 per cent of the calories contained in the original cane sugar 6 Experiments have shown that the value of glucose and cane sugar in nutrition is essentially the same. These perfectly well known facts can be readily verified by any one

Dr Wiley further inveighs against the use of commercial glucose because it is cheap This being a question of political economy, is outside my sphere of knowledge

Graham Lusk, New York

Comment —Dr Wiley's *Good Housekeeping* article deals with the attempt on the part of the officials that have to enforce the federal and state "Pure Food Laws" to establish a standard for mince meat Dr Wiley stated that, after reviewing the matter with some care, these officials reached the decision that commercial glucose was not a normal ingredient of mince meat This being so, the presence of glucose in mince meat would have to be declared on the label The question was not one of the wholesomeness, or otherwise, of glucose, it was the broader one of whether or not the public should be inveigled into buying a cheap filler (glucose) at mince meat prices Commercial glucose is not a condiment and can hardly, in the ordinary sense of the word, be called a sweetener In fact, it is so insipid that cane or some other real syrup has to be added to it to make it palatable It certainly has no higher nutritive value than the same amount of sugar It thus appears that each of Dr Wiley's statements is justified from a scientific standpoint and, beyond all question, his attitude toward the use of commercial glucose in foodstuffs is one that is in the public interest —Ed

Queries and Minor Notes

Anonymous Communications will not be noticed Every letter must contain the writer's name and address but these will be omitted on request

TEMPERATURE VARIATIONS IN TUBERCULOSIS PREPARATION OF SALVARSAN RHEUMATISM PHYLACOGEN

To the Editor —1 What is your explanation of the presence of a subnormal temperature in one subject and a temperature above normal in another under the same conditions of rest in cases of phthisis pulmonalis that appear equally advanced?

2 What is the usual duration of such temperature in these cases under favorable conditions when the body weight continues to increase?

3 Please give latest technic in preparing salvarsan for subcutaneous or intramuscular injection Is it possible to obtain a clear solution?

4 What is the virtue of Rheumatism Phylacogen ?

L. D., N

Answer —1 The temperature in tuberculosis is markedly increased by a number of conditions It is the index of an auto-inoculation in a sensitive patient If there is little or no resisting power, the introduction of the tuberculous toxins into the circulation may produce no rise of temperature, but rather a fall due to the depressing toxic influence If, on the other hand the patient is sensitive to the toxin of tuberculosis, any circumstance which tends to increase the amount of these toxins in the general circulation will cause a rise of temperature Thus most tuberculous patients show an increase of temperature after exercise, because the exercise causes an auto inoculation by forcing some of the toxins from the tuberculous focus into the circulation The temperature may also be influenced by the activity of the disease in the local focus Thus one patient may have a lesion which is in a state of activity that will produce a rise of temperature, while another may have a lesion of the same character, but not active, in which the temperature may be even subnormal In other cases the rise of temperature is presumably due to a mixed infection by other organisms cooperating with the tubercle bacillus to produce the rise of temperature

2 Since the causes of the temperature are so various it would be impracticable to state the duration, which depends largely on the treatment and the course of the disease

3 Our correspondent is referred to the Syphilis Number of The Journal, Oct 5, 1912, which contains much information about salvarsan, and which, in the Queries and Minor Notes Department, contains references to other articles in previous issues, out of some of which he can doubtless find an answer to his questions

4 Rheumatism Phylacogen was discussed in this department Aug 10, 1912, p 464

IODEX AND IODIN PETROGEN

To the Editor —Please give the composition and therapeutic value of iodex and iodin petrogen

W J Merrill M D, Philadelphia

Answer —These preparations have not been submitted to the Council on Pharmacy and Chemistry, which is in itself an indication that the claims made for them would probably not be verified The claim is made that they will not stain the skin after they are applied locally As a rule such preparations do not contain free iodin Usually the base is of such character that if iodin is added to it a chemical combination occurs so that iodin is no longer free

Iodex is said to be an ointment of iodin, containing 5 per cent of therapeutically free iodin What the significance of this term 'therapeutically free" is we cannot tell Until further evidence is offered we feel safe in stating that the preparation probably does not contain any considerable amount of free iodin

Iodin petrogen is claimed to be a solution of iodin in petrogen —a proprietary preparation essentially equivalent to liquid petrox Two varieties are offered iodin petrogen 5 per cent and iodin petrogen 10 per cent From the nature of petrogen, which contains ammonium soap, it is probable that the greater part of the iodin enters into chemical combination

TREATMENT OF WINTER PRURITUS

To the Editor —I have a patient who is subject to an intolerable itching over the entire body most intense about the waist line which occurs only in cold weather and principally after taking a bath There is no evidence of eruption nor is there any skin affection Her general health is good This has been troubling her for a good many years but of late it has been growing worse I have tried many remedies but as yet have found nothing of special benefit It appears to be an irritation of the peripheral nerve endings but what is the causative influence?

B Lima Ohio

Answer —Evidently the case is one of so called winter pruritus It is essentially a hyperesthesia or hypersensibility of the skin and the itching is due in part to the dryness of the skin which increases its vulnerability, and in part to the irritation produced by cold In its slight form winter pruritus is exceedingly common The severer cases in which the irritation amounts to an affliction are rare The itching is excited not only by cold but by bathing, the wearing of rough underclothing and similar irritants

The treatment, in large part consists in avoiding as far as possible all sources of local irritation The underclothing should be as smooth and non irritating as possible, light cotton underwear or better light linen or silk should be worn next to the skin Bathing with soap and water ought not be indulged in beyond the point of necessity The bath may be made less irritating by the addition of bran, starch or marshmallow The bath should be taken in as short a time as possible and the body dried by dabbing the surface, not by rubbing Then the body should be powdered with talcum, starch or some other inert powder If the patient dresses quickly and does not go to bed for an hour or so the itching is less than if he gets immediately into bed after the bath In many cases the greatest comfort is obtained from anointing the body after the bath with a preparation such as olive oil, liquid petrolatum or a well made rose ointment Sometimes these applications are made more soothing by the addition of an antipruritic drug usually phenol, menthol or camphor A good application of this sort is made from olive oil or rose ointment containing from 0.5 to 1 per cent of phenol, menthol or camphor menthol, or from 2 to 4 per cent of thymol or camphor chloral A good liniment for use in some of the cases is phenol, ½ to 1 dram, zinc oxid and calamine, each 1 ounce, olive oil, 8 fluidounces and enough lime water to make 1 pint It requires trial to determine which applications are most comfortable Internal remedies are of no use.

USE OF TUBERCULIN

To the Editor —As the authorities judging from the literature think differently in regard to the following questions please give me the answers according to general professional usage

1 Should tuberculin be given when fever is present?

2 Should it be given after the patient has been in bed for quite a while say two months and the fever still persists?

3 As a routine which tuberculin is best as a therapeutic measure in pulmonary tuberculosis?

4 What is the interval (consensus of opinion) between injections when there is no reaction?

5 With the minimum dose a reaction is manifested Is it a contra indication for its further employment?

W H Smith, M D Goldsboro N C

Answer —1 As a rule, tuberculin should not be given in the presence of fever, as the fever is an indication of a toxemia due to the existence of the tuberculous toxin (tuberculin) in the blood

2 In such a case the physician must exercise his own judgment but if he believes that the fever is due to an active tuberculous process the use of tuberculin would be contra indicated

3 Some form of the old tuberculin (Koch's) is generally to be preferred The new tuberculin may be used, due precautions being taken as to dosage

4 The injections are usually repeated at intervals of about a week or ten days

5 Reactions should be avoided in the use of tuberculin In such a case the use of tuberculin should be suspended, or, at any rate, a smaller dose which will not provoke a reaction should be used

PROPHYLACTIC TREATMENT OF ECLAMPSIA

To the Editor —Please tell me in what number of The Journal I can find the extract from W Stroganoff's paper on the Prophylactic Treatment of Eclampsia I remember reading the article at the time it appeared and am anxious to see it again Also refer me to any other article by Professor Stroganoff on this subject

Adam P Leighton Jr M D Portland Me

Answer —Stroganoff's technic was described in The Journal, July 3, 1909, p 86, and abstracts in reference to it have been published recently

Stroganoff W Prophylactic Method of Treating Eclampsia *Ztschr f Geburtsh u Gynäk* 1912 lxx No 1 abstr in The Journal, May 18 1912 p 1575 *Ann de gynéc et d'obst* 1912 xxxix 300 *Zentralbl f Gynäk* 1912 xxxvi 800
Voigts Stroganoff's Prophylactic Method of Treating Eclampsia *Berl klin Wchnschr* 1912 xlix, 1771

Zoeppritz B Prophylactic Treatment of Eclampsia *München med Wchnschr* 1912 lix 400 1708

ARTICLES ON VENTILATION

To the Editor —Please give me titles of articles on humidity and the effect of tropical sun and heat and confinement with and without circulating air etc Also carbon dioxid accumulation in connection with the circulation of confined air

Edmund P Fowler, New York

Answer —We have published in The Journal two editorials on the subject of ventilation One of them appeared Sept 16, 1911 p 980, the other, March 9 1912, p 702 There was also published in The Journal an article by H Sewall On What Do the Hygienic Virtues of the Open Air Depend? Jan 20, 1912, p 174 Other articles on the subject appear in the following periodicals

Paul *Ztschr f Hyg* 1905 xlix 405
Crowder T R *Arch Int Med* January 1911, p 85
Billings, Mitchell and Bergey The Composition of Expired Air and Its Effect on Animal Life Smithsonian Institution Publications 1895
Rosenau and Amos Organic Matter in the Expired Breath, *Jour Med Research*, 1911 xxv 35
Weichard *Arch f Hyg* 1911 lxxiv 185
Inaba *Ztschr f Hyg* 1911 lxviii 1

THE ULTRAMICROSCOPE

To the Editor—Please give me what information you can in regard to the ultramicroscope It has been mentioned editorially in THE JOURNAL recently W B

ANSWER—The ultramicroscope was invented by Dr H Siedentopf and is manufactured by Carl Zeiss It renders visible particles which are beyond the limits of vision with the ordinary microscope, even with the highest powers, and are hence described as ultramicroscopic The effect is obtained by arranging the condenser at right angles to the optical axis of the microscope, so that its concentrated light enters the slide containing or forming the object laterally—through the edge The light diffused by small particles is the only light that reaches the eye, and the latter will therefore be sensitive to its utmost limit

It is further necessary to limit the illumination to particles within the depth of focus, as otherwise the light scattered by *particles not in focus would form a luminous background* This object is attained by focusing the source of light, generally the electric arc, on an adjustable spectroscope slit, then focusing the slit in the object

In this way particles of gold having sides equal to from 1/6 to 5/1,000,000 inch are made visible By its means minute particles of other origin, such for instance as the flagella of certain bacteria, can also be demonstrated Other devices for dark ground illumination are employed, and these are sometimes considered as synonymous with the ultramicroscope This, however, is not correct, although they afford in some cases a useful substitute for it

ARTICLES ON TOBACCO

To the Editor—If within the last six years any articles on tobacco have appeared in THE JOURNAL, please tell me in what issues I can find them A G SINCLAIR Memphis Tenn

ANSWER—The article "Tobacco" in the department of Therapeutics of THE JOURNAL, May 8, 1909, p 1495, is a rather full statement on the subject In addition the following editorials have appeared

The Pharmacology of Tobacco Smoke THE JOURNAL, Jan 30 1909 p 386
The Use of Tobacco THE JOURNAL July 2 1910 p 32
The Effects of Tobacco on Body and Mind THE JOURNAL Oct 1 1910 p 1206
Some New Evidence on the Tobacco Question, THE JOURNAL Nov 16 1912 p 1798

The last named editorial contains two references to articles which appeared in the London *Lancet* (April 6, 1912, p 944 and Aug 24, 1912, p 547) These report experiments in the *Lancet's* laboratory New methods of research were employed, and the whole question of tobacco shown in a new light

LITERATURE ON HORMONES AND HORMONAL

To the Editor—Kindly give me JOURNAL references to hormones especially with regard to hormonal for and against also secretin gastrin H KINGSLEY HINE, M D Waterbury Conn

ANSWER—The subject of hormones was discussed in this department, Oct 19, 1912 p 1474, while hormonal was discussed Aug 10, 1912, p 465 where a considerable bibliography is given In addition we find another article

Jurasz, A T Death After Intravenous Injection of Hormonal *Deutsch med Wchnschr* May 30 1912 abstr in THE JOURNAL July 6 1912, p 75

With reference to gastric secretin, e find only two recent articles

Wentworth A H The Cause of Infantile Atrophy THE JOURNAL, July 20 1907 p 204
Meltzer S J Animal Experimentation in Relation to Our Knowledge of Secretions Especially Internal Secretions THE JOURNAL May 7 1910 p 1507

EFFECT OF MAGNESIUM SULPHATE

To the Editor—In an article entitled "The Treatment of Eclampsia" in a recent journal a well known obstetrician makes the following statement The stomach should be washed out and from one to two ounces of a saturated solution of Epsom salt left in the stomach to be repeated at intervals when the patient can swallow

In the light of our present knowledge of Epsom salt poisoning (through the work of Boos) may not such treatment prove dangerous? INQUIRER Boston

ANSWER—The treatment advised is certainly heroic and it is possible that in some cases poisoning might result. Usually however, a dose of one ounce of magnesium sulphate would merely secure a very loose evacuation with the removal of considerable water from the tissues Such a saturated solution placed in the stomach would not be likely to be absorbed but would excite a marked secretion of water into the stomach If the solution was passed into the intestine the chances for absorption would be greater We believe it would be better to limit the dose to one ounce of the salt which would be contained in about an equal quantity of the saturated solution

TIZ AND MUM

To the Editor—Can you give me any information relative to the composition of the following preparations Mum advertised as a perspiration deodorizer and Tiz a sore foot remedy?
RODMAN F SHEEN M D, Atlantic City N J

ANSWER—In the *Pharmaceutische Zeitung* Oct 26 1907, p 904, an analysis is given of the salve known as 'Mum, used as a deodorant It was reported to contain salicylic acid zinc oxid, glycerin water a tallow like fat and traces of essential oils The quantities of these ingredients were not given

Tiz" was analyzed by the Association's chemists and the results reported in THE JOURNAL Dec 2, 1911, p 1853 It was found to have essentially the following composition

Alum	60 per cent
Tannic acid	10 per cent
Salicylic acid	5 per cent
Talcum	5 per cent
Starch	20 per cent

FREQUENCY OF DOSAGE OF DIGITALIS

To the Editor—In the discussion on the action of digitalis in THE JOURNAL, Oct 26 1912 page 1565 it is recommended to give the drug every two or three hours Kindly reconcile this with the statement often made that digitalis does not begin to produce its effects for twenty four hours and hence that one dose a day is all that should be given J R Y

ANSWER—So far as we know, it is not commonly recommended to give digitalis only once a day The frequency of its administration should depend on the rapidity with which it is necessary to secure the maximum effect on the heart In acute cases it may be necessary to give it once in two or three hours, but as a usual treatment the administration of the remedy three times a day is sufficient Accumulative effects appear to be due to the slow elimination of the drug so that after the physiologic action of the remedy is apparent doses should not be repeated any more frequently than the drug can be eliminated from the system

LITERATURE ON ENTERTAINMENT FOR THE INSANE

To the Editor—I have been asked by our local society to deliver a paper on insanity and I have decided to write on the value of entertainment for the insane Please refer me to articles on the subject W H S ——— Ohio

ANSWER—The following may be referred to

Zeller C A More Work and Recreation for the Chronic Insane *Kansas City Med Index Lancet* October 1910
Cohn F Systematic Occupation and Entertainment of the Insane in Public Institutions THE JOURNAL April 18 1908 p 1249
Barrus Clara Nursing the Insane Macmillan Co New York 1908 (This book has a chapter on the occupation and amusement of patients)

Dr William L Russell of the National Committee on Mental Hygiene 50 Union Square New York, would probably be able to give further information on this subject

NORMAL BLOOD SERUM IN HEMOPHILIA

To the Editor—Please give me a list of recent articles on the use of normal blood serum in the treatment of hemophilia and hemophilia neonatorum C F S[illegible] Litchville N Dak

ANSWER—In THE JOURNAL, Oct 26, 1912, are published a number of articles and a Current Comment on the subject The use of normal horse serum is discussed on page 22 of New and Nonofficial Remedies, 1912

THE RUSSO REACTION IN TYPHOID

To the Editor—Please give me the formula for Russo's typhoid fever test and state its efficiency
J T[illegible] GOODE M D Booneville Miss

ANSWER—The method of Russo's reaction in typhoid its time of appearance relative value and the necessary reagents were given in THE JOUR[illegible] 912, p 465, in answer to a similar query

SOCIALIZING THE BRITISH MEDICAL PROFESSION

In last week's issue the general effects of the new Insurance Act of Great Britain were discussed, with special reference to the possibility of such a plan being considered in this country[1] In one important particular the British situation differs materially from that in this country there have existed in Great Britain for many years, medical clubs, insurance organizations, and the so called "friendly societies," which have made a business of furnishing medical attendance to members in return for a low annual fee As the total membership of these organizations is estimated at about 6,000,000, and as most of these would come under the operation of the Insurance Act, it is evident that the attitude of the clubs and "friendly societies" constitutes an important factor in the situation in England In an article in a recent number of the *Medical Press and Circular*, of London, Mr Harold B Grimsdale, ophthalmologic surgeon of St George's Hospital, discussed the conditions which led to the passage of this law After commenting on the advance in modern scientific methods and the vastly increased cost of a modern education, Mr Grimsdale took up the discussion of the Insurance Act He said

"It has been a strange spectacle which has been presented to the world during the months that have passed since the passage of the Insurance Act—a spectacle without parallel in the history of medicine We have seen the united profession—united more completely than ever before—standing firm together in their resistance to an act which professes to carry out the work which is specially the province of the profession, namely, to provide benefits which it is the boast of our profession to give freely to all, very often without thought of reward, seldom with an adequate one It is indeed a strange spectacle, and the profession must have been sorely tried before they rose, almost unanimously, in protest against such an act

We are told almost daily by one section of the press that we are employing the worst methods of trades unions, that we have adopted all the vices of syndicalism, and none of the virtues, if it has any, that we have forfeited the right to the name of a generous profession Now, however much some of us may regret the conduct of this dispute between the government and the profession, however much small incidents may distress us and rankle in our minds, there can be no doubt that, on the main questions, the medical profession come out with clean hands We are certainly not on strike, for what is a strike? When the coal miners struck, coal went up to such price that the poor were unable to buy it at all and the rich were forced to economize When the taxi drivers came out, taxis could hardly be procured But there is no evidence that any medical man has refused to treat any sick person

What is it, then, that has united the profession as it has never been united before? Why are all medical men throughout the country breaking away from all their natural instincts, unwilling to take service under the act? To explain this it is necessary to go into a piece of somewhat ancient history We must examine the origin of clubs and voluntary hospitals, and so discover the reasons why the terms of the act are so little to our taste

"It is, in a sense our own fault that our services are regarded as of so little value It goes back to the commencement of medical charities All clubs had their inception, in so far as the medical benefits were concerned, in the charitable work of medical men When, about the beginning of the last century, or earlier, the difficulty of the medical treatment of the thrifty poor was recognized, a species of insurance was started so that the cost of an illness might not cripple any one individual, being spread over many Medical men, altruists by training were willing to give their services to these clubs for little or nothing It was recognized that the work was a form of charity, and it was not pretended that the fees received by the medical men were in any degree adequate reward for the services rendered, but were to prevent them from being largely out of pocket by their kindness Many such clubs in the country have been run by my personal friends, who were out of pocket at the end of each year, but were content to continue their charitable actions, knowing how great was the value of their services to the poor

"Another form of contract practice is not uncommon in some parts of the country, especially in the colliery districts Here the medical officer is the servant of the colliery, and the manager deducts an amount varying with the weekly wage from the pay of each collier

"Thus a roughly equitable scale is worked, a man earning £1 a week or less pays 1d, and for each £1 or fraction of £1 he pays another 1d In this way the collier whose total earnings average £156 (£3 a week), will pay 13s a year for his doctor This sliding scale is in accordance with the usual medical practice to charge according to the capacity of the patient When the large friendly societies began to cater for the same medical benefits, they were able to point to the small honoraria accepted by the medical officers of these clubs, to induce men to undertake their seemingly similar duties for the same insufficient payment

"The astute business men who were in charge of the clubs pointed out to the young practitioner how valuable was the *advertisement and introduction which followed his acceptance of the club terms, and were usually able to persuade him to* come to an agreement The terms were absurdly low, some clubs even made money out of their medical attendants, that is, they levied a certain sum, say 1d a week, from each member, and paid the medical man 3s or 3s 6d a year, saving the balances for other uses of the club If no local medical man were willing to take the work, they were often able to import an outsider who would take the post, and the mere hint of such a proposition would weigh heavily with a struggling man who would be called on to face new opposition It did not occur to the managers of the club—or at least they showed no signs of appreciating the fact—that the advertisement would have been just as good for the doctor if he were reasonably paid By degrees, the status of the club altered, instead of being confined to the really poor, the limits were so widened that any one was able, for the absurd pittance at which the club was started, to demand the services of the medical officer

"Men who joined poor became rich, but were still entitled to the medical benefits Often, it is true, the more successful men, who belonged to the club, were willing to forego their benefits, while continuing their subscription for the good of their poorer brethren, and called in, when occasion required, a medical man at his usual fees This might or might not be the medical officer of the club, but this was a purely voluntary sacrifice on their part, and though many did not demand sick pay in illness, feeling a natural hesitation to take from the club funds a few shillings a week which their fellows would know to be of small importance to them, a much smaller proportion refused the medical benefits, they were not unwilling to accept the benefits which could not so easily be traced

"No medical officer of such a society could make a living without a very large club, and, on the other hand, with a large contract practice, the number of patients to be seen was so great that the medical man could not give adequate attention to each It was physically impossible to go carefully through all the differentia in making an investigation, and hence, since the work had to be done, it was very tempting to make a snapshot diagnosis, or give a placebo

By degrees this system of clubs became so prevalent that in many large towns there were hardly any inhabitants left who were not swept into the net of the insurance companies, and thus brought into the range of medical benefits All private practices were swallowed up by the clubs

"What wonder, then, that there came an outcry from all those most interested in the welfare of the profession, that by the contract system all initiative was being destroyed and that the medical men engaged in this work were being ruined mentally and financially by it, in the name of charity? What wonder that the men who found themselves fleeced on every side were anxious to escape from it? And yet it had some advantages The contract system did away with the necessity for a great deal of bookkeeping, always irksome to a busy man, and at the same time there was a certain income with no risk—so far as the contract extended—of bad debts Hence many practitioners, with wife and family dependent on them, dared not, as individuals, make a stand against the clubs And who shall blame them?

"At the time when the insurance bill was first heard of it was recognized by all that some system of state insurance against sickness was most desirable Medical men were all in favor of the idea A workable scheme providing a service throughout the country, had indeed been suggested by some of them and had been tried in certain localities, medical men, therefore taking into consideration that they would have to be the chief workers under the act and that they had already some little experience in the treatment of the people who would come under it, remembering also that they had protested on every opportunity against the system of contract practice, not unreasonably expected that they would be asked through their organizations, to advise on the best methods of working However, as I shall tell you, they were not consulted they might have thought—since they were going to bear all the risk—that the state would deal not only fairly but generously with them

---

[1] Socializing the British Medical Profession editorial The Journal A M A Nov 23 1912 p 1890 Those who wish to read further of the progress of the movement are referred to our weekly London Letter during the past few months.

'They were doomed to disappointment, the action of the government is barely credible, and not at all creditable

"The bill was brought in in May, 1911 In spite of repeated requests, the chancellor of the exchequer saw the representatives of the British Medical Association for the first time in April This was the only deputation from the Association received before the introduction of the bill, and at this meeting no special opportunity was afforded to the Association for ascertaining the provisions of the bill Nor, apparently, was the General Medical Council, nor the Royal Colleges of Physicians and Surgeons treated with more courtesy Presumably the chancellor had medical advisers Who they were has not, I think, been made known, but they certainly were not the associations of medical men, who would have commanded the respect, and been in some sense at least the representatives of medicine

"When the medical provisions were known, it was at once seen that they were most unfavorable to the best interests of medicine In the first place, the payment was to be *per caput* This alone must stamp any scheme as liable to failure It is not in the interest of any man's work that he should be paid at a higher rate the less work he does It cannot induce to keenness and initiative, if the keen man is penalized because of his keenness

"The more care taken in diagnosis and investigation, the less the reward It must not be forgotten that investigation on modern lines costs money and this had to come out of the funds for payment of medical men

"The chancellor of the exchequer has, throughout, shown himself ignorant of the first requirements of modern medicine It is, if one may judge from his attitude, his opinion that doctors are engaged in a guessing competition, with numbered bottles which agree with the number of the disease from which the patient suffers

'Lastly, the suggested remuneration is inadequate Of course, it is perfectly true that nowhere is it laid down in the act what the rate of remuneration is to be, but it is acknowledged that only a certain rate is justified by the actuaries

'The chancellor has been very generous—at our expense—to the working man in an approved society Under the present act the laboring man pays about ¾d a week for his medical attention He is often willing to pay 7s 6d a year for the fun of keeping a dog, it is not too much to expect that he should pay as much for keeping his health

"And, again, let me mention the case of firms who own large numbers of horses They usually pay the veterinary surgeon a contract fee to look after them, and this is usually 21s a head Now a horse cannot malinger, and cannot demand unnecessary medical attention

"Or we may look at the matter another way The government has been hitherto willing to pay 8s 6d a year for the medical attention of each employee in the post-office who are men of picked physique and in good health It is not likely that the government has been paying to the medical men who have had charge of these and other public servants, twice the value of the services rendered Why should we be asked now to undertake the treatment of all lives—healthy and unhealthy—who are compelled by the act to insure themselves, at about half the sum which the government has previously thought equitable for healthy lives?

'Surely, on all counts we are fully justified in our rejection of the scheme designed by the government and in our determination to build up a better public medical service by our own efforts '

Although frequent references have been made to this measure in various departments of THE JOURNAL, during the past two years, the principal points in the controversy may not be fresh in the minds of our readers A summary of the situation may therefore be of value

Mr Lloyd George introduced his bill in May, 1911 A special representative meeting of the British Medical Association was called for May 31 and June 1 1911, in which the general features of the bill were approved with reservations and the 'six cardinal points' stating the objections of the Association to the bill were formulated. The points on which the British Medical Association agreed to stand were

1 An income limit of £2 ($10) a week, as the maximum for those entitled to medical benefits

2 Free choice of physician by patient subject to the consent of the physician to act

3 Medical and maternity benefits to be administered by local health committees and not by "friendly societies"

4 The method of remuneration of medical practitioners adopted by each local health committee to be according to the preference of the majority of the medical profession of the district

5 Medical remuneration to be what the profession considers adequate having due regard to the duties to be performed and other conditions of service

6 Adequate medical representation in the various boards and committees charged with the operation of the act

At the annual representative meeting of the Association at Birmingham in July, 1911, the action of the special committee was reaffirmed A second special representative meeting was held in London, Nov 23 and 24, 1911 The action on the six cardinal points was again reaffirmed and the Association voted to use all means to prevent the establishment of any form of medical service under the act, except under arrangements consistent with the six cardinal principles Since the passage of the act in December, 1911, the position of the British Medical Association and of practically the British medical profession has been one of refusal to work under the provisions of the law in its present form As a result, the law, while enacted, is at present practically inoperative, pending an adjustment of the differences between the provisions of the law and the demands of the profession The law as it stands creates an insurance fund by contributions from the insured, the employers and the state, the control of which fund is in the hands of the insurance commissioners The power of fixing the income limit is left to the local committee in each district, but the general position taken by the government has been in favor of a maximum income limit of £160 ($800) per year, while the British Medical Association has insisted on a maximum limit of £2 a week, £104 ($520) a year The controversy over freedom of choice of physicians has been modified by the adoption of regulations by the committee, but is not as yet satisfactorily adjusted. The third point was practically conceded in the passage of the bill, and the administration of the medical benefit is in the hands of insurance committees and not in that of friendly societies The method and amount of remuneration are the points over which the fiercest controversy has been waged The method under the law is to be determined by the insurance committee after consultation with the local medical committee This is not regarded as of so much importance as the amount since the sum paid to each physician has been shown to be about the same under any one of five proposed methods Regarding the amount, the representative meeting fixed 8s 6d as the minimum capitation fee, without including medicines or extras The chancellor of the exchequer, October 23, offered 8s 6d per insured person, out of which 1s 6d was to be definitely allotted for drugs and instruments, 6d additional being held for drugs in case the first amount proved insufficient and the remaining 6s 6d being for the compensation of the physician This is a considerable increase over the terms first proposed but lacks 2 shillings (48 cents) of the minimum amount adopted by the British Medical Association The sixth condition that of representation, has probably been granted but a seventh relating to dispensing, has been added The present situation seems to be that after eighteen months of constant warfare, the British Medical Association has succeeded in having the provisions of the law materially modified either by changes in the bill itself, or by the adoption of regulations by the insurance committee The question of whether the modifications are sufficient to make the present arrangements sat[illegible]tory to the physicians was referred to a third [illegible] meeting which was to be held Novem

The following questions were asked

ANATOMY AND EMBRYOLOGY

1 Give the anatomic divisions of the spinal column and the bones in each division 2 Name the bones of the middle-ear and give their connections 3 Describe the different kinds of joints giving examples of each variety 4 Describe the sartorius and the occipitofrontalis muscles 5 Describe the thoracic duct 6 Give the branches of the aortic arch 7 Give origin course and distribution of the sciatic nerve 8 *What bony cavities communicate* with the nose? Describe the development of the frontal sinuses 9 Give the early steps of development after impregnation 10 Trace the fetal circulation

CHEMISTRY AND MEDICAL JURISPRUDENCE

1 Give a simple test for organic impurities in water 2 What is the difference between urea and uric acid? 3 What chemical tests are most important in the analysis of urine? 4 Describe the test for bile blood *pus and urea in urine 5 Give test for detection of* morphin 6 What is the effect of inhaling air rich with ozone on the respiratory organs? 7 What is the reaction of blood during gout? 8 In a medicolegal sense what constitutes a dying declaration and what is necessary to make it evidence in a court of justice and how should it be taken? 9 At what period will a *body float* after being drowned? 10 What are symptoms of poisoning by wood alcohol and treatment for same?

PHYSIOLOGY AND HISTOLOGY

1 Define afferent, efferent tropic inhibitory and motor and vaso motor nerve-fibers 2 State the functions of the vas deferens the vesiculæ seminales and the prostate gland 3 Define secretion excretion and assimilation 4 What digestive changes take place in the small intestine and the large intestine? 5 What is the physiologic function of the liver? 6 What changes are produced in the air and in the blood by respiration? 7 Give the histologic structure of a tooth 8 Describe a malpighian body 9 Describe hyaline cartilage 10 Describe the histologic structure of a lobule of the lung

SPECIAL MEDICINE

1 Describe the physical signs and symptoms on which you would base a diagnosis of aneurysm of the thoracic aorta 2 Diagnose *renal calculus stone in the ureter pus kidney* 3 Define diagnose and treat adenoid growths of the nasopharynx 4 What is hay fever? Give the etiology and treatment 5 Describe the technic of making intralaryngeal applications 6 Give the etiology diagnose and treat edema of the larynx 7 Give the etiology diagnose and treat simple conjunctivitis acute epidemic conjunctivitis and *trachoma 8 Define give the etiology diagnose and treat iritis* 9 Describe the effect of lead poisoning on the nervous system 10 Describe the technic of lumbar puncture

SURGERY

1 Discuss the principles underlying the local and general treatment of surgical infection 2 Give the pathologic and clinical difference between sarcoma and carcinoma 3 Name three suture materials in common use give a method for the sterilization of each *and discuss the relative* advantages and *disadvantages* of these materials 4 Give the diagnosis of cerebral compression due to extradural hemorrhage and differentiate it from compression due to depressed bone 5 Name the varieties of dislocations of the shoulder joint and describe the symptoms of the most common one 6 Give the etiology and diagnosis of empyema of the pleura 7 Give the pathology and early diagnosis of intestinal obstruction 8 Give the causes and diagnosis of rupture of the urinary bladder 9 Give the diagnosis and treatment of a fracture in the lower half *of the femur 10 Give the pathology and treatment of ingrowing* toenail

BACTERIOLOGY AND HYGIENE

1 By what agencies does the body protect itself against the entrance and harmful effects of pathogenic bacteria? 2 What are some of the phenomena attending pus formation? 3 Describe the formation of an abscess 4 State the most common sources of infection in diphtheria 5 Name some diseases that are communicable to human beings through cow s milk 6 How much fresh air is *required for normal respiration during twenty four hours? 7 What* infectious diseases may be due to impure drinking water? 8 Describe the agency of the ptomains in inducing diseases and the disorders produced by them 9 Name six carbohydrates used as food 10 What are the principal measures which you would employ for the prevention of the spread of infectious diseases?

OBSTETRICS AND GYNECOLOGY

1 Give the symptoms of pregnancy in the first three months. 2 Give the *indications for premature interruption of pregnancy* 3 Tell how you would manage a case of face presentation 4 Give the causes and treatment of post partum hemorrhage. 5 Give the prophylactic care of the breast before and after labor 6 Give the symptoms and treatment of puerperal eclampsia 7 Differentiate fibroid ascites fat and cysts 8 Under what conditions would you advise a hysterectomy in cancer of the uterus? 9 What are some of the peculiarities of gonorrhea in a female? 10 How would you treat extreme prolapse?

PRACTICE OF MEDICINE AND PEDIATRICS

1 Give the symptoms and treatment of chronic myocarditis. 2 Give the treatment of intestinal hemorrhage in typhoid fever 3 Give the period of incubation and of eruption of the exanthemata *4 What is uremia and how should it be treated? 5 Differentiate* heat exhaustion from sunstroke 6 What is the significance of the patella reflex as a sign of disease? 7 What are the indications of beginning hip-joint disease? What is the treatment? 8 Give the treatment of summer diarrhea in infants 9 What would you do in the case of a baby having convulsions about once or twice a week? 10 Give the symptoms and treatment of infantile scurvy

MATERIA MEDICA AND THERAPEUTICS

1 Give *rule for dosage of children* 2 Write a *prescription containing* four drugs. 3. What are somnifacients analgesics antipyretics? Give example and dose of each 4 What are serums? Name three and give dose 5 Digitalis preparations doses and physiologic action 6 Coal tar derivatives name four principal ones and give physiologic action 7 Cathartics name three varieties give therapy 8 Strychnin give therapy 9 *X* ray describe it and give therapeutic uses 10 606 describe methods of use Is it preferable to mercury and iodids?

PRACTICE OF MEDICINE AND PEDIATRICS (ECLECTIC)

1 Discuss acute articular rheumatism in children including complications and sequelæ 2 Define cretinism Give etiology diagnosis and treatment 3 Make diagnosis direct and differential of *small pox. 4 Give the etiology diagnosis and treatment of hip-joint* disease 5 Give the etiology and name the cardinal symptoms of tabes dorsalis 6 Give the symptomatology diagnosis and treatment of myocarditis. 7 Define herpes zoster Give the etiology and make diagnosis 8 Give symptoms diagnosis and treatment of poliomyelitis 9 *Diagnose* and treat scarlet fever 10 *Diagnose* and treat pneumonia in children

MATERIA MEDICA AND THERAPEUTICS (ECLECTIC)

1 Give properties specific symptomatology and dose of apocynum 2 What is the source of salicylic acid? Give therapeutic indications for the use of salicylates 3 What is the composition of Dover s powder? Give dose and indications 4 Name three emetics Give dose and indications for use. 5 What is the therapeutic *value of heat and cold? Methods of application? 6 Discuss thera*peutic value of elimination Describe effective measures 7 Discuss therapeutic use of KI 8 Name three bromids. Give properties dose and therapy 9 How would you proceed with the management of hyperpyrexia? 10 What remedies are available for the removal of tapeworm? Give dose and methods of administration

---

Overwork as a Cause of Neurasthenia—Talking of the causes of neurasthenia, Dr Savill says 'The first of these is fatigue or overwork, and that you are no doubt familiar with in every day practice Just as a faradic battery will become weaker and weaker if it is used and will be restored by rest and warmth, so will the nervous system become weaker and weaker if it is overworked, that is, if there is prolonged forced *functioning*"—*Thomas D Savill in Clin Jour*

Book Notices

Public Health Chemistry and Bacteriology A Handbook for D P H Students. By David McKail M D D P H F R F P S G Lecturer on Public Health and Forensic Medicine St Mungo's College Glasgow Cloth Price $2 50 Pp 400 New York William Wood & Co 1912

This work is intended as a text book for students taking laboratory courses in public health examinations, both chemical and bacteriologic The author has endeavored to make it as complete as possible while leaving out matters which can be more satisfactorily taught and demonstrated than written about For this reason no illustrations have been introduced, as the various instruments and apparatus are seen and used in actual work An examination of the volume shows that the various methods are well described and the work is sufficiently complete to form a reliable guide for such examinations of foods, etc, as the physician may have an occasion to make

Recent Advances in Hematology Being the Dr James Watson Lectures for 1910 By Walter K Hunter M D D Sc Physician to the Glasgow Royal Infirmary Cloth Price $2 25 net Pp 110 with a Colored Plate William Wood & Co 1912

This volume represents the James Watson lectures for 1910, delivered before the Royal Faculty of Physicians and Surgeons of Glasgow The book covers the domain of hematology as represented in the most recent text books and many articles in current medical literature The statements are for the most part brief and practical For instance, the subject of viscosity of the blood is discussed in two paragraphs with the conclusion that the estimation of the viscosity of the blood has not thus far come into general use in clinical medicine While the book will not replace the more extensive treatises on clinical diagnosis or the special works on the blood, it will be of service in giving a clear idea of the present status of this important subject.

A Collection of Papers (Published Previously to 1909) By William J Mayo and Charles H Mayo Two Volumes Cloth Price $10 net Philadelphia W B Saunders Company 1912

These are reprints, the articles having appeared in various medical journals, although it seems incongruous to apply this term to such handsome volumes, which in appearance compare with the finest text books The books are uniform in type and are handsomely illustrated These articles are arranged according to subject and the table of contents shows what a broad field of surgical subjects the Mayos have been discussing in the literature of the country Instead of yielding to the temptation to prepare text books, as is too often the custom, the Mayos have simply gathered here the results of their prolonged study, analysis and experience, as contributions to the general subjects The fortunate possessor of these volumes will peruse them with pleasure and profit, knowing that he is learning from men who are painstakingly thorough and conscientiously exact

Digestion and Metabolism The Physiologic and Pathologic Chemistry of Nutrition For Students and Physicians By Alonzo Englebert Taylor M D Rush Professor of Physiologic Chemistry University of Pennsylvania Cloth Price $3 75 Pp 560 Philadelphia Lea & Febiger, 1912

To quote from the preface "The author is convinced from perusal of current medical writings in this country that there is need among American physicians for a work presenting the subjects of digestion and metabolism in a popular manner, without technical details, and from the standpoint of dynamics rather than from that of analytic statics usually occupied by text books of physiologic chemistry" This need Professor Taylor has endeavored to meet by rewriting in the form of a concise, systematic treatise the substance of his lectures on this subject The book presents a thorough scientific account of the subject, beginning with the composition of foodstuffs and the nature of ferment action, and tracing the changes occurring in salivary, gastric and intestinal digestion and in the processes of metabolism inside of the organism After a detailed consideration of the metabolism of various elements of the food the subject of metabolism considered as a whole is taken up in a chapter of moderate length In this are discussed the relations of protein, carbohydrate and fat, with such subjects as inanition, normal diet and nutrition Another chapter considers the production of body heat regulation of body temperature, the nature of fever, etc The book is well written and presents many conclusions of importance to physicians

Medicolegal

Sufficient Authority for Action of Coroner's Physician

(Hassard vs Lehane (N Y), 135 N Y Supp 711)

The First Appellate Division of the Supreme Court of New York, after having on a previous appeal, reversed a judgment of nonsuit and granted a new trial, as reported in The Journal of August 5, 1911, page 502, now reverses a judgment rendered in favor of the plaintiff, and grants another new trial The action was brought by a mother to recover damages from a coroner's physician for an alleged wrongful dissection of the remains of her son and detention of parts of the remains The excuse offered on the first trial appeared to be that it was an interesting case" which was held insufficient But on the second trial a quite different defense was set up The evidence tended to show that the defendant had received from the coroner's clerk a list of cases for investigation, including the case of the plaintiff's son who was reported to have met his death by falling from a vehicle The defendant then went to the hospital where the remains were, examined the hospital records and talked with the house surgeon, and was told that the deceased was found in a drug store by a policeman, whither he had been carried from the street by a citizen who disappeared, that there were no marks of violence on him, that he died about two hours after being received at the hospital that the house surgeon was unable to account for the cause of death, and "that there was a question of suspicion about it ' The defendant then reported to the coroner over the telephone what he had learned, and was directed by that official to make a "complete" autopsy, and discovered that the immediate cause of death was a hemorrhage from a ruptured spleen, but was unable without a microscopic examination to determine whether the rupture was traumatic or due to disease He again reported the facts discovered to the coroner, and was directed by the latter to make a microscopic examination of the spleen, and, pursuant to that direction, he removed the spleen from the body and sent it to a laboratory for examination The trial court charged the jury that the direction of the coroner was not a subpena, but that if given, it might be considered on the question of the defendant's good faith in assessing damages, and that an autopsy even if directed by the coroner, was not justified unless necessary to disclose the cause of death and then only to the extent required for that purpose The Appellate Division holds that there was error in these instructions It suggests that the word "summon' would have been more appropriate than "subpena" in the governing statute, but that at any rate, a formal subpena was not indispensable to the protection of the coroner's physician The question was whether the coroner actually directed the dissection of the body and the microscopic examination of the spleen, and the uncontradicted evidence was that he did It was for the coroner to determine whether the death occurred under such circumstances as to justify an inquest and an autopsy It was the defendant's duty to obey the direction of the coroner and to ascertain the cause of death Obviously he was concerned only with the medical side of the case and was not required to interpose his judgment against that of the coroner as to whether the deceased had died from criminal violence, etc His duty was to make an autopsy "as may be required," which should be construed 'as may be required by the coroner' If [illegible] fore the coroner directed the dissection [illegible] ero [illegible] am ination of the spleen, those [illegible] he defendant, constituted a complete

KENTUCKY STATE MEDICAL ASSOCIATION

Forty Seventh Annual Meeting held at Louisville, Oct 28 31 1912

(Concluded from page 1918)

Vaccine Therapy

Dr John H Blackburn, Bowling Green Vaccine therapy is not a panacea for bacterial diseases Much may be accomplished by the prophylactic use of the vaccines in certain types of infection They also have a distinct value in the treatment of many infections, acute and chronic, local and general Each case requires careful study and attention, a microscopic and cultural diagnosis being always made, if possible, and the proper dosage used at the proper intervals

Pellagra as Related to Insanity

Dr W E Gardner, Lakeland Physicians in hospitals for the insane do not, as a rule, see the case of pellagra until the mental symptoms are well developed, and it is with the mental condition that they are chiefly concerned, while the physician in private practice sees the patient from the point of view of the body first, and the mental condition afterward The form of insanity that predominated in the cases already in the institution, when pellagra developed, was that of dementia praecox The manic depressive types, with the depressive forms predominating, seem to come next in order, in our cases, but with less tendency to suicide than seems to occur in cases outside of institutions, and reported by authors *Melancholia of involution* or the 'anxiety psychoses" come in for a few cases with some distressing symptoms of fear and impending danger We have had only one case occurring in a patient with general paralysis, which was of short duration, due to the advanced stage of the latter disease The treatment in our twenty cases has been largely symptomatic and supportive

The Present Status of the Operative Treatment of Fractures of Shafts of Long Bones

Dr A H Barkley, Lexington The advantages of the open method are apparent The operator can place the bones in exact apposition, as the whole field is directly under the eye, all overriding or angulation is at once overcome In some types of fractures of the shafts of long bones, in spiral and oblique for instance, it is obvious that no amount of traction will reduce the fragments, and no known dressing will hold them with any degree of certainty in apposition as will the method of direct fixation The patient is relieved of annoying pain due to the movement of the fragments This is especially noticeable in many cases treated in a non operative way, and is sometimes due not so much to any movement of the patient's body as to the involuntary contractions of muscles This disagreeable feature is obviated when internal splints are used, as the bones are held firmly apposed There is less extravasation into the tissues when direct fixation is employed early than when treated otherwise, and the possibility of any intervening fragments of tissue and bone which defeat union is entirely obviated The deformity is practically *nil* and the bones are left more nearly normal and in no wise interfere with the wage earning capacity of the individual As a rule fractures that have been plated have no exuberant callus In cases in which other methods have failed and much deformity is likely to follow, this method offers the best result

I cannot subscribe to the views of those who never look at a fracture except in the light of an operation, and while the open method in selected cases is beyond doubt the best procedure, its employment in every case must be condemned In order to use internal splints, one must be prepared by training in surgical work and carry asepsis to the highest degree, that it should be done in a well equipped hospital and require special instruments goes without saying The application of internal splints requires specially constructed instruments, such as bone drills, elevators, long forceps for assisting in approximating the ends of bones, a special screw driver, etc. The set of instruments used by Lane will be found adequate for this operation

Alcohol, Its Therapeutic Uses and Limitations

Dr. W F Boggess, Louisville Alcohol is unquestionably a therapeutic agent of no little value to be used as a medicine with the same care, and with the same safeguards around its use and abuse as in the case of other poisonous drugs, such as morphin, cocain and strychnin In my opinion no drug requires greater acumen and therapeutic knowledge for its use than alcohol The continued use of alcohol has a tendency to destroy fine cell structure everywhere, as well as the finer moral and intellectual functions and faculties There are some types of fevers in which alcohol is of benefit, and certain types of patients with whom it also could be used with benefit The converse is equally true A great deal has been written for and against the use of alcohol in typhoid fever Some have asserted that it should be used from beginning to end, others that it is a drug which can be entirely dispensed with in the treatment of this disease None of these statements is correct There are many cases of typhoid fever in which, if the patients receive in the second or third weeks of the disease sufficient quantities of alcohol to support the system by lessening tissue metamorphosis, supplying something that is easily oxidized and thus saving food products and combating asthenia, there is great benefit and lives are saved It has been my practice for years in certain types of tuberculous states to prescribe half an ounce of brandy, well diluted, three times a day It assists the appetite, relieves pain by its quieting effect, and *increases the fat forming tendency by its own oxidation and* the effect it has in assisting digestion and lessening metabolism in the tissues The common routine and liberal use of alcohol as a remedy in influenza is to be discouraged and condemned There are many other remedies indicated in the depressing effects and complications of this disease that are as good as alcohol in the majority of cases, if not better

Fractures

Dr J Garland Sherrill, Louisville The object of the treatment of a fracture is to obtain repair of the injury and restoration of function with the minimum amount of deformity, loss of time and discomfort to the patient To obtain these results most perfectly, accurate apposition of fragments, restitution of contour, the prevention of redisplacement by complete reduction and proper appliance, and proper position, with rest, are necessary When should one employ the closed and when the open method of treatment? It is needless to say that no patient should be subjected to a cutting operation unless there is some clear and distinct reason for such procedure This, I believe, would be accepted as an axiom without argument, no matter how many and cogent reasons one might offer in support of the simplicity of interference Here, as *in all departments of surgery, it is the* surgeon's duty to exercise care and good judgment in selecting the method of treatment To illustrate my meaning let me cite fracture of the patella, which I have never treated by incision and suture of the bone, because I have thus far always been able to bring the fragments together satisfactorily by hooks, subcutaneous suture or splint. In one or two instances I have almost decided to lay open the overlying tissues in order to obtain approximation by direct appliances, but I have finally not been obliged to do so The open operation I believe to be legitimate, and probably needful in a few selected cases, but I am opposed to it as a routine treatment I would strongly urge frequent inspection of fractures especially during the early and later time of treatment, the first to avoid deformity, the second to pro mote restoration of function In the treatment of a fracture of the clavicle, that form of appliance must be employed which will hold the shoulder upward, backward and outward without being irksome to the patient In fractures of the shaft of the humerus, in my opinion there is no dressing equal to the Stromeyer cushion or a pad of towels along the chest with the arm bandaged to the chest. The forearm should be placed in a bandage and placed in a sling at the wrist, thus allowing the weight of the arm to make extension at the elbow and prevent the overlapping of fragments

How the United States Public Health Service Can Help in the Eradication of Preventable Diseases in Kentucky

Dr Joseph Goldberger, Washington, D C The first step in the eradication of preventable diseases is to know of their prevalence, and hence it is extremely important that there be provided some means of obtaining and distributing this information In the nature of the case the reports of sickness must in the first instance come from the local communities, and machinery must be provided to give the state this information But the state is *not an isolated unit, it* must know not only what is going on within its own borders, but also within those of its immediate neighbors, at least This information the U S Public Health Service attempts to supply through its weekly publication, the *Public Health Reports* Morbidity reports give the sanitary officer information with respect to the existence and the degree of prevalence of disease In order, however, that measures looking to the eradication of preventable sickness may be planned intelligently and the money of the community most advantageously spent, the sanitary officer must know what factor or factors are at work favoring their prevalence and to estimate the relative importance of the various factors involved The Service is ready and willing to help your health board in this great work Its willingness to help is unlimited and the amount of aid which it is able to render is circumscribed only by the limits of its available personnel and appropriations Your state can have this assistance for the asking, it can have more, if it will do its share through its representatives in Congress toward supplying the Service with more men and more money

The Public Health Problem Constructive Efforts Toward Its Solution

Dr. W L. Heizer, Bowling Green The chief objects of cooperation of these forces, it would seem, are (1) to educate the public in the proper methods of preventing disease through *the public schools, press, pulpit and from the platform,* (2) to furnish a sufficient number of competent speakers, and large audiences to greet them, (3) to elect county and state officials who will establish a county department of health with a competent health officer, well paid, to devote his entire time to the prevention of disease in his county a laboratory where immediate microscopic and chemical analyses can be made, free of charge, of water and milk and of bodily excretions from persons ill, (4) to secure the enactment and enforcement of sanitary laws to guarantee pure food, water and air to the people, (5) to secure larger investments by the state in good roads better schools, higher salaries for more competent teachers, and increase in appropriations to the state department of health

---

SOUTHERN MEDICAL ASSOCIATION

Sixth Annual Meeting held at Jacksonville Fla Nov 12 14 1912

The President, Dr J W Jackson, Miami, Fla , in the Chair

The list of officers elected was given November 23, page 1800

Diagnosis of Malaria

Dr Graham E F Henson, Jacksonville, Fla In cases of suspected malaria the blood should be examined carefully for the detection of the parasites It should be the aim to secure laboratory confirmation of the clinical findings before placing the patient on specific treatment, provided there are no symptoms suggesting the more pernicious type of the disease In the event that quinin has been administered before the patient comes under *observation, a tentative diagnosis of malaria,* even in the absence of the detection of the parasites, is justifiable when (1) the clinical history of malaria is obtainable (2) the patient has an enlarged spleen, (3) a leukopenia is present (4) the red cell count is below normal, (5) the hemoglobin is reduced, and (6) the differential count shows an increased percentage of large mononuclears

DISCUSSION

Dr E C Thrash, Atlanta Ga A case came under my observation three or four weeks ago in which a diagnosis of tuberculosis had been made For six or eight weeks the diagnosis lay between malaria and typhoid I found the spleen much enlarged, and ruled out tuberculosis I thought that the patient had either typhoid or malaria He had been taking quinin systematically and regularly in all sorts of ways I gave him treatment for ten days, watched him, and found that he had high temperature continuously and occasionally a chill At the end of the eighth or ninth day I began to make examinations of the blood every six hours, and in the fourth examination I found estivo autumnal parasites I put him on 4 grains of sodium cacodylate hypodermically daily, and on large doses of quinin hypodermically to which he responded promptly and he has had no trouble since

Dr. Charles F Craig M C, U S Army A man became unconscious on the street, was picked up and taken to the emergency hospital He died in a short time I had the opportunity of examining the brain and spleen and found both loaded with estivo autumnal parasites Another patient was in the hospital for a week before a blood examination was made This patient died, and post mortem examination *revealed the spleen filled with these parasites*

Dr James H Randolph, Jacksonville Three cases of the cerebral form of malaria recently came under my observation, which illustrated the importance of blood examinations These cases were characterized by delirium

Dr William E Ross, Jacksonville A child had six convulsions in five hours, was unconscious, and had absolutely all the symptoms of acute epidemic cerebrospinal meningitis with a temperature of 102 F My diagnosis was cerebrospinal meningitis I was about to make a lumbar puncture. I took a blood smear, and found malarial parasites of both the estivo autumnal and tertian type The child was unconscious for six days before it responded to quinin treatment

Dr L. A Green, Jacksonville The records of our state hospital show that a number of patients admitted as insane were suffering from pernicious malaria These patients reacted promptly to quinin and recovered, but left the institution with the stigma that they had been insane, when, as a matter of fact, they had been suffering from malaria

Dr Joseph Goldberger, Washington, D C There can be no doubt that a routine examination of the blood is absolutely essential, but the general practitioner does not, as a general rule, avail himself of this means of diagnosis, believing that it is unnecessary

Dr C C Bass, New Orleans As to the time of taking blood from the patient, if we are dealing with the estivo autumnal type, the parasites may now be present in the blood for six or eight hours In estivo autumnal cases in which the clinical course is more or less tertian, with chills and intermittent fever, with, perhaps, normal temperature, the parasites segment almost altogether in groups as they do in the *tertian and quartan types* In such cases the *number of parasites* present in the blood after six or eight hours would be smaller than at any other time There never occurs a time when parasites cannot be found in the blood of the patient who is having chills and fever from malaria The proper time to make a blood examination for malaria is whenever you see the patient

Malaria in Alabama

Dr R H von Esdorf U S P H Service, Mobile, Ala *All forms of malarial fevers prevail in Alabama* The types of infection in the order of prevalence are tertian, estivo autumnal, subtertian, quotidian and quartan A large factor in the spread of infection is the colored race, in which the chronic type of malarial infection is proportionately greater than in the white race To obtain an index of infection in the community, a blood examination should be made of adults as well as children Latent or non chronic cases should be treated vigorously for at least a month, and then with prophylactic doses of quinin from April to November Prophylactic doses of quinin should be taken between April 1 and November 1 by all persons in Alabama living in the localities known to be infected The prophylactic dose I use is 5 grains of quinin sulphate, given morning and evening The microscope should be more generally used for making a diagnosis or confirming the diagnosis of malaria, or, if practicable, advantage should be taken of the state laboratory, where examinations of blood will be made

Malaria in the Puerperium

Dr. J V Freeman, Jacksonville, Fla When there is elevation of temperature during the puerperium in a woman who has caused her physician a great deal of anxiety and trouble during her pregnancy, and he discovers malarial infection, he is justified in giving prophylactic doses of quinin if he delivers her a second time, but he is not justified in giving it in every case he sees

DISCUSSION

Dr Graham E E Henson, Jacksonville, Fla Owing to the fact that any rise of temperature in the puerperium causes great alarm not only to the attending physician, but also to the members of the family, it has been my custom for the last five years, as soon as a patient is delivered, to put her on 10 grains of quinin a day By following this line of procedure in delivering 100 or more women, I have never seen malarial fever develop in the puerperium I generally give 5 grains in the morning and 5 grains at night

Dr Stevens T Harris, Highlands, N C It is erroneous to make a diagnosis of malaria simply from fever returning periodically I have seen fever, chills and sweats, typically malarial in character, recur without the presence of malaria You may also have chills occurring periodically and with regularity in tuberculosis and possibly in other septic conditions I would strongly urge that the microscope is the only way to diagnose malaria

Dr B B Simms, Talladega Ala Chills and fever may be present, and even if we find the plasmodia we cannot call the case malaria every time, because plasmodia frequently occur in the blood In Alabama it has been found that 11 per cent of the people have malarial parasites in the blood without manifesting symptoms of malaria

Dr W A Boyd Columbia, S C If a puerperal woman shows a febrile condition and we are not sure of the actual condition present I do not believe that we are justified in putting that woman on the routine treatment of quinin until we have proved by bacteriologic examination that she is infected with malaria

15 *Modification of Bartlett s Gastro-Enterostomy Clamp J J Buchanan Pittsburgh

1 **Tetany Following Thyroidectomy**—Shepherd says he always thought there was little danger of removing all the parathyroids or injuring them in performing total thyroidectomy, for he had in quite a number of cases removed the whole thyroid and in others left only the isthmus or a part of one of the lateral lobes, and he never saw a case of tetany or cachexia strumapriva However, last January he operated in a case in which he was forced to remove nearly all the thyroid, and this operation was followed by severe tetany In this case no trace of any parathyroids was found in a most careful examination of the removed gland so that he concludes that the parathyroids were so injured at the operation that they were rendered useless The third day the patient complained of a feeling of formication over the whole body and of a great weight which pressed on her brain She had slept well the night before and had a normal pulse and temperature Toward evening she complained of severe pain at the base of both lungs and next day felt dizzy and had numbness of the legs and feet On the fifth day, in the morning she felt fairly well but complained of numbness and tingling in the legs and face and a feeling as if ants were crawling over her skin A few hours later she had cramps in both hands and pains in the joints and considerable stiffness of the fingers and flexion of the toes Then there were severe paroxysms in both arms and legs The thumbs were contracted in the palm of the hand, the fingers flexed at the metacarpophalangeal joint, the wrist flexed, and elbows bent The toes were flexed and adducted and the feet extended She complained of great pain in the legs, which was at times spasmodically increased, her face twitched and there was numbness and stiffness about the jaws Chvostek's sign was well marked, and pressure on a nerve trunk produced spasms (Trousseau's sign) Pulse was 80 to 100, and she had no temperature Her voice was very husky and she seemed stupid, she complained most of the acute pain in the legs, which at times was very severe.

Shepherd put her on dram doses of the lactate of calcium every three hours This was about eleven in the morning and at 5 p m the spasms and cramps had disappeared, the fingers were relaxed, the voice became natural, and she said she felt very well, only tired After five doses the lactate of calcium was discontinued as she disliked it so The seventh day after operation, she began to feel the sensation of formication again, with a feeling of weight in front of head and great depression She was again put on calcium lactate, dram doses, with 2½ grains of thyroid extract, every four hours She had slight cramps in her extremities that night with pain in the left side Next day she was free from cramps but still had pressure symptoms in the head and a creepy sensation over the body For the next two days she remained about the same and refused to take any more calcium lactate On the eleventh day she was worse than ever, all previous symptoms being much exaggerated She was given 1/20 grain parathyroid extract, every four hours, with 3 grains of thyroid extract As she was no better next day she was persuaded to commence taking the calcium lactate again in addition to the extracts, and in consequence the improvement was rapid, the cramps disappeared, and she felt very much better The patient left the hospital on the twenty first day and was directed to take 30 grains of calcium lactate and 1/20 grain parathyroid extract every four hours Twice the lactate of calcium was discontinued and the symptoms always returned, though parathyroid was still administered This case agrees with the conclusions found by Voegtlin and MacCallum, that calcium can cure temporarily any case of tetany due to insufficiency or removal of the parathyroids.

2 **Treatment of Aortic Aneurysm** —Following the method used by his namesake, Macewen introduced a fine steel needle, highly polished, into the interior of the inner surface of the opposite wall of the aneurysm, so as to produce a series of slight abrasions of that surface In seven weeks, a needle was twice introduced and a large area of the posterior wall was treated. The patient expressed herself as feeling better after the treatment She returned to the hospital three months later, had a needle introduced once, remained in hospital for a month, and was able to go home in a cab She now felt so much better that she was able to walk a little, and go about and enjoy herself She returned to the hospital in October, 1910, remaining there for a month, and on this visit had two needles introduced simultaneously on two occasions, at an interval of a fortnight Thereafter patient began to feel very much better In July, 1912, patient expressed herself as feeling better than she had for many years back Not only can she go about freely, but she can go up and down stairs actively without assistance or inconvenience, she can perform ordinary light household duties, there is no pain nor choking sensation, and she further states that she has entirely recovered from severe headaches which had caused her much suffering prior to the appearance of the aneurysm Pulsation is still noted in the neck, as is to be expected, owing to the deep or posterior wall being the one which was treated, but it is not marked, and only becomes noticeable when patient is excited

3 **Primary Sarcoma of Peritoneum** —Four months before Venable saw this patient, the man was kicked by a horse in the right side of the abdomen just within the anterior superior iliac spine From this time patient had suffered pain and tenderness in this locality, but not, however, till about two and a half months after the injury did he suffer any digestive disturbances This presented as an intermittent diarrhea accompanied by anorexia and nausea and abdominal pains, from which time he dates the beginning of his loss of weight This continued for two or three weeks, when patient himself discovered a mass in his right iliac region, which is described as then feeling about the size and shape of a lemon and which was movable and not tender During the succeeding twenty four days it attained the size of two cantaloupes placed end to end Lost thirty four pounds in weight Complained of a dull ache in his right side and sense of weight Anorexia pronounced, accompanied by seizures of nausea but no vomiting Frequent stools, six to ten or fourteen daily, watery in character, some mucus and occasional traces of blood The abdomen was opened, exposing a neoplasm springing by a large pedicle, soft and vascular, from the peritoneum just over the brim of the pelvis, about two fingers' breadth to the outer side of the sacro iliac synchondrosis There were no other intestinal or mesenteric or omental attachments or adhesions Removal of the growth including the base of the pedicle was easy, after which further examination revealed no evidences of metastasis He was discharged on the eighteenth day The pathologist's report was "spindle cell sarcoma " The gross appearances of the tumor were typical of sarcoma In about three weeks after returning home, the patient suffered a recurrence of the diarrhea from which he had suffered prior to operation, accompanied progressively by anorexia, severe abdominal pains, and seizures of extreme nausea, which continued till the time of his death, Jan 26, 1912, a little over three months after his operation

6 **Volvulus of Stomach.**—Kerr's patient gave a history of frequent attacks of pain and indigestion after eating About one hour after eating the largest meal of the day the patient was seized with sudden cramps in his stomach Induced vomiting and deep, prolonged massage in the stomach region finally brought relief These attacks lasted about twelve hours, but the patient did not recover sufficiently to return to work for several days The patient admitted excessive, constant gin drinking, and is a tremendous eater, gulping his food without mastication On examination there was noticed a most remarkable distention of the upper abdomen, reaching from the ensiform cartilage to the umbilicus, and everting the costal arches, this tense swelling extended to the mammillary line on the right On palpation the limits of this mass extended slightly beyond those noted on inspection, it felt hard and very tense The abdomen below the umbilicus was not distended but the muscles showed some rigidity On percussion this distended area was highly tympanitic Heart action was rapid, weak and irregular, a beat was quite frequently dropped All attempts to pass the stomach tube was futile

The abdomen was opened The tense stomach was exposed not covered with omentum and was punctured with a large trocar Gas under great pressure escaped with a whistling sound, and the distention began to subside A catheter was then introduced in place of the trocar and a great quantity of gas and 54 ounces of brown grumous fluid were evacuated Incision, in what was thought to be the anterior wall of an acutely dilated stomach, was sutured with silk and the abdominal wound closed The abdomen had then resumed its normal contour, and the heart had moved back to its usual place The patient's condition, however, did not improve Death occurred fourteen hours after onset At the autopsy the stomach was found completely inverted and markedly dilated, so that the posterior wall became anterior, and the greater curvature was pressing against the diaphragm The gastrocolic omentum was torn free from the greater curvature of the stomach, and the transverse colon was found lying below the stomach After a careful review of the literature, Kerr found eight similar cases of true idiopathic volvulus

10 **Treatment of Fistula in Ano** —Of 105 consecutive cases on which Elting's report is based, ninety six were found to be histologically non tuberculous and nine histologically tuberculous Of the nine tuberculous patients, seven had demonstrable pulmonary tuberculosis at the time of the operation Of the 105 cases, sixty four occurred in males and forty one in females Arranged according to age, two occurred in the first decade, one of them in a child of 10 months, eight occurred in the second decade, thirty seven occurred in the third decade, thirty occurred in the fourth decade, fifteen occurred in the fifth decade, ten occurred in the sixth decade and three occurred in the seventh decade In practically all of these cases it had been possible to trace the subsequent history of the patients, and in all of them, so far as Elting has been able to determine, the fistulas have healed and remained well Some of the patients have died, but none from causes associated with the fistulas except in patients with pulmonary tuberculosis, four of whom have died There was no mortality associated with the operation In one case an abscess formed in one of the ramifications of the fistulous tract, which required incision about one month after the operation, but which subsequently healed and has remained well This was the only case in which any kind of a second operation was required

In seven of the cases some degree of stenosis or stricture developed subsequently, but all of these were cases with very extensive perirectal inflammation and necrosis, in most instances associated with bowel openings from 2 or 3 inches above the anal margin The use of hard rubber rectal dilators inserted by the patient once or twice daily effectually relieved the stricture in all of the seven cases, so that at this time none of them has occasion to use the dilators These strictures were the result of the extensive scar tissue due to the widespread inflammation One of these patients now has marked incontinence of feces due to an almost complete degeneration of the external sphincter muscle associated with partial degeneration of the internal sphincter Three others of these seven have more or less incontinence of feces, when the bowels are loose, due, so far as can be determined, to the same cause The remaining cases of the entire series have practically normal sphincteric function From several years' study and experience in the treatment of fistula in ano, Elting concludes that probably not more than 10 per cent of fistulae in ano are tuberculous and that a great majority of these are secondary to demonstrable tuberculosis elsewhere in the body, usually in the lungs The great majority of fistulae in ano originate from a diseased condition of the rectum existing in the lower 1½ inches, and that this diseased condition is usually a hemorrhoid The essential principles [illegible] of fis

Dr. Robert Heilig Library

JAIPUR
324

in ano consist in (a) the severance of the communication between the bowel and the fistulous tract and (b) the removal of the diseased portion of the bowel, including the fistulous opening A widespread and often destructive dissection and removal of the fistulous tracts in the perirectal tissues is unnecessary It is possible to cure fistulae in ano without injury to the sphincters and with a preservation of all the sphincteric function possessed prior to operation, by the application of the Whitehead principle of rectal excision

12 **Ivory Finger Dowel**—Primrose's patient had an enchondroma of the proximal phalanx of the index finger of the right hand Through this region a fracture had taken place An ivory peg was procured, 2 5 cm long and 3 mm thick, which was pointed at both ends An incision was made along the radial side of the phalanx and the bone exposed at the seat of fracture The tumor was removed by a curet, and then a longitudinal slit 4 mm wide was made in the compact tissue of the distal fragment, by means of a Dahlgren's rongeur forceps, the ivory peg was inserted and firmly secured in the center of the shaft of the bone, each sharp end being embedded in the cancellous tissue toward the articular extremities of the phalanx The wound was then closed and a splint of plaster of Paris applied Healing took place *per primam* Firm union of the fracture followed, and subsequently the patient was able to use the finger in his work as accountant The functional result as to movement and utility was perfect and it was difficult to detect any abnormality at the seat of former trouble

13 **Reduction of Fragments in Fractures**—Two methods for reducing fractures are described by Gerster One is a traction method in which he separates the fragments forcibly by means of a special apparatus (hook and chain) which overcomes overriding and makes accurate approximation possible The other is a reduction method After proper exposure and freeing, a Lowman clamp is applied to each fragment A turnbuckle is so inserted that the jaws at its ends engage the shafts of the clamps on either fragment As the barrel of the turnbuckle is rotated, the clamps (fragments) are forced apart When the turnbuckle has reached its maximum extension, a second longer turnbuckle is applied and continues the extension as far as necessary The turnbuckle's jaws are made loosely to fit the shafts of the Lowman clamps in order to permit of the fragments (which are out of line) being gradually brought into their proper relation

15 **Bartlett's Gastro Enterostomy Clamp**—The clamp described by Buchanan has a fixed center bar and a separate pair of thumb screws from each viscus This allows the fold of stomach to be fixed in place first between the fixed center bar and one of the movable side bars It thereafter requires no attention while the intestine is being fixed between the center bar and the other movable side bar To render it possible to slip the rubber tubing over the middle bar and to facilitate removal, the latter is made in two sections, which are screwed together after the tubing is applied, and require to be separated for removal of the clamp after the anastomosis has been made

Pitfield Germantown Philadelphia
21 Congenital Hydronephrosis with Aplasia of Ureter [illegible] Van Der Bogert [illegible]

16 **Infant Milk Depots**—The ideal milk depot in [illegible] opinion is one equipped with rooms for preparing the milk, pasteurizing it in the nursing bottles and distributing it from [illegible] depots very near the home of the mother at cost or to the destitute free The ideal equipment for accomplishing this would be a large plant for preparing and pasteurizing the milk, with a consulting room and dispensing room attached and with refrigerator wagons for transporting the milk There should also be a number of sub stations for distribution and consultation, with still more sub stations for distribution only Each of the consulting stations should be provided with a physician, who would spend certain hours there each day, and a nurse, who would spend all her time on the work in the depot and the homes This scheme provides the most economical method of preparing and distributing the milk It provides consulting rooms, where the mother may take her baby once a week for weighing and for advice, as well as nearer distributing stations where the milk may be obtained on other week days without going as far as the consulting station. Very efficient work can be done with less equipment, where the funds are limited, when certified milk is distributed and clinics are held by physicians and nurses are provided who are active in the milk depots and at the homes Thus the New York *Diet Kitchen Association* which, with a small income from subscriptions and endowment, was doing a very limited work in dispensing milk to babies and invalids, has recently rapidly expanded its work through a policy of charging those who can afford to pay, so that during the past year, with an income of some $82,000, $45,000 of which was contributed by the mothers who bought the milk, they have been able to dispense more than a million quarts of milk from nine stations, and their results have been wonderfully good Consultations with physicians are held, and trained nurses have been attached to some of the depots and will soon be attached to all The mortality in the patients treated at these depots has been extremely small Of 2,421 babies under their care between June and October last, four months, including the summer months, they report only thirty deaths from all causes, a mortality of 12 to 10 per cent for these hot summer months Where funds are available the scheme first mentioned should be carried out As to the results of milk depots in lowering mortality, it has been found that where they are generally established so as to supply all the babies that need their help a reduction of about 60 per cent is obtained.

22 **Neurologic Aspects of Injuries to Cranium and Spinal Column**—From a study of the clinical disturbances and pathologic findings in traumatic injuries of the cord, Taylor concludes that hemorrhage external to the cord is unusual and need not be seriously considered in deciding on [illegible] concussion of the cord without [illegible] possibility that [illegible] microscopic le[illegible] ing th[illegible] the damage to the cord is immediat[illegible] [illegible] injury that delay in operation is advisa[illegible] operation is unavailing when signs of complete t[illegible] lesion persist and that laminectomy may help toward[illegible] tion of the functions of a partially damaged cord

23 **Surgical Treatment of Head Injuries Affecting** [illegible] Unless there is pressure to be relieved hemorrhage stopped or fluid to be drained off Homans says there [illegible] ing to be gained by operation In properly selected cas[illegible] ever the following results are to be expected An ede[illegible] swollen brain is given sufficient room so that it is n[illegible] pressed In such a case rapid recovery is probable Bl[illegible] from ruptured meningeal vessels is removed and hem[illegible] is stopped Here rapid recovery is to be expected Whe[illegible] cussion and laceration exist together the brain is n[illegible] given more room but blood and cerebrospinal fluid, [illegible] longer properly disposed of may be drained away [illegible] recovery is uncertain and slow Finally, and in general, [illegible] ery in all kinds of cases is tremendously hastened and [illegible] is some reason to believe that many of the late ne[illegible] epilepsy or other mental defects, so greatly dreaded b[illegible] are done away with

39 **Formation of Glycocoll in Body**—The experiments recorded by Epstein and Bookman did not afford any definite evidence of the conversion of native leucin into glycocoll. In the absence of such evidence it appears likely that much of the glycocoll liberated on feeding benzoic acid is the result of a synthetic process in the body.

40 **Efficiency of "Amid Nitrogen" for Growth**—This paper includes the records of the comparative efficiency of nitrogen from alfalfa hay and the corn kernel for growth. Also data on the relation of creatinin output to nitrogen storage in heifers. On the basis of total nitrogen ingested the utilization of nitrogen for growth was as efficient when the [illegible] was from alfalfa hay as when it came from the corn kernel. With high intake of total digestible crude protein [illegible] the case of alfalfa includes the "amid nitrogen" the storage of nitrogen was essentially alike on the two rations. There was no sudden decrease or increase in the nitrogen [illegible] of the urine or feces when the animals were suddenly changed from one ration to the other. This is evidence that the "amid nitrogen" was being used in the same way as the true protein nitrogen. It is apparent from these data that full [illegible] for growth, can be given to the total nitrogen of alfalfa [illegible]. The "amid nitrogen" should not be considered [illegible] influence on milk production will be studied later. [illegible]ing heifers there was no very concordant [illegible]put with increased storage of nitrogen. [illegible] possibility of using this index for the [illegible] of the efficiency of a given source of nitrogen [illegible]gen storage.

41 **Metabolism of Amino Acids**—[illegible] opinion that the increase in metabolism [illegible] meat is due to the [illegible] action of [illegible] on the cellular protoplasm.

42 **Metabolism of Mixtures of Food Stuffs**—[illegible] cludes that there are the following [illegible] quiet or sleeping dog [illegible] A basal metabolism, [illegible] stream which [illegible] but the composition of [illegible] the body, (2) [illegible] increased quan[illegible] blood on account of absorption from the intestine, and (3) a metabolism due to the stimulus of amino acids. The metabolism of plethora and the metabolism of amino acid stimulation cannot be added to each other; there is no summation of effect when both influences are brought into action simultaneously. In other words the level of cellular oxidation induced by plethora is not further heightened by the stimulus of amino acids, unless the latter alone would accomplish such increase in activity.

46 **Maintenance with Isolated Proteins**—The authors' experimental records suggest that in the past the possibility of a transmutation or synthesis of amino acids in the organism has been greatly underestimated, and that these chemical processes may play a more significant part in nutrition than has been credited to them hitherto. The realization of the possibility of a transmutation of amino acids has an obvious bearing on the question of the quantity of protein in the diets, for the arguments in favor of a liberal protein intake have in part been based on the belief that all of the "Bausteine" must be supplied in adequate amounts. To what extent the daily "wear and tear" of metabolism may require a new supply of Bausteine to replace depleted tissue, remains a matter of conjecture at present. Studies to determine the amount of nitrogenous material involved in what Rubner has termed the "Abnutzungsquote" show that it is not large in quantity. The experiments here recorded give no answer to the possible extent of the synthesis of new amino acids, except, perhaps, in the case of glycocoll and lysin. Further investigations with the various proteins must be undertaken to determine the relative minimum quantities of each of them essential for long continued maintenance.

70 **After-Effects of Too Radical Tonsillectomy** —Complete tonsillectomy, according to Stucky, should be advocated as a routine procedure He claims that tonsillectomy should be regarded as a major operation and as such should be performed in a hospital with careful surgical technic. In many, probably in the majority of cases where tonsillectomy is performed, there is more or less injury done to the pillars of the fauces In removing the tonsils and capsule some shreds of muscular tissue are usually cut or torn off and are adherent to the removed gland Even should this not occur, the muscle is left uncovered, hence unprotected, over the area to which the capsule of the tonsil was adhered. Tonsillectomy is not a simple operation nor is it free from danger, yet it is being performed more frequently by general practitioners and embryo specialists than any operation in surgery Stucky has seen one case of facial paralysis lasting for five weeks This patient was operated on by a well known laryngologist, and there was a cellulitis following the operation Two months after, the cicatricial tissue between the anterior and posterior pillars had the appearance of that so often seen following syphilitic ulceration He has seen three cases in which a claim was made of marked impairment of the voice, especially of the high tones

In two other cases the pillars of the soft palate were out of alignment due to cicatricial contraction, causing tension and interference with palatal movements, making swallowing a discomfort The anterior and posterior pillars were matted down by adhesions, causing the traction to be so great around the fossa of Rosenmueller as to cause a partial closure of the eustachian tube with subsequent tinnitus In three other cases the uvula had been caught in the loop of the snare as it was being placed around the tonsil and was removed with the tonsil In two other cases there was a loss of tonicity of the tensor palati and levator muscles, which resulted in the regurgitation of fluids through the nares, lasting for several weeks This was evidently due to the great traction made with the tonsillar forceps which was necessary to pull the tonsil out so as to make a dissection There was one case of fatal hemorrhage a few hours after the operation, two cases of cellulitis involving the entire neck, and nine cases of secondary hemorrhage requiring a second anesthesia and tying a spurting vessel or plugging the space between the pillars and sewing the pillars together

89 Pregnant Woman, Tuberculosis and Safety D H Stewart New York

81 **Operation for Procidentia, with Rectocele and Cystocele** —In Goffe's operation the underlying motive is to restore not only anatomic structures, but also physiologic function In the first class of cases, after attending to any minor lesions, the uterus is restored to its normal position by shortening the round ligaments through the vagina, and in extreme cases the utero sacrals as well This is done with the prominent idea in view of reconstructing the normal anatomic arrangement and thereby reestablishing the important function of the uterus and broad ligaments as a deflecting plane of intra abdominal pressure In dealing with the cystocele, the effort has been made to observe with scrupulous care also the anatomy, function, and topographic position of the bladder The trigone of the bladder is spread out and made fast to the anterior face of the uterus and broad ligaments, by carrying the base of the bladder up and stitching it at three points, one stitch at each cornu, and one in the median line at the center of the anterior face of the uterus The uterovesical peritoneal fold is restored as well as the hinges on which the dome of the bladder moves in its function of receiving and discharging the urine This gives a fixed point of exit for the urine and a rigid canal in the passage of the ureters through the wall of the bladder

In the restoration of the floor of the pelvis Goffe uses the method of distinct isolation of the levator ani muscles and stitching them together with buried sutures

In the second class of cases, that is, in patients at, near, or beyond the menopause, unless there is positive objection on the part of the patient the uterus is removed per vaginum In order to restore the deflecting plant of tissue the broad ligaments are stitched together across the pelvis from the infundibulopelvic and round ligaments down to cardinal ligaments In this procedure a plane of tissue is restored in exactly the same situation and under control of the same ligaments as under normal conditions This deflects from its posterior surface back into the pelvic outlet, the intraabdominal pressure, and thus physiologically takes place of the original structures On its anterior face it also affords a surface on which to spread out and fix the trigone of the bladder, restoring its hinges and all its physiologic functions The floor of the pelvis is restored in the usual manner

88 **Poisoning by Scarlet Red** —Lyle's case was that of a woman, 50 years old, suffering from extensive burns of the anterior chest, both forearms and wrists, caused by exploding benzine They were treated by the dry method until the sloughs separated A scarlet red ointment (8 per cent scarlet red in U S P boric acid ointment) was applied to a small portion of the granulated edges As the wound reacted kindly the area of application was extended. On the sixteenth day of the employment of the scarlet red ointment the patient complained of headache, dizziness and general faintness The following morning she was seized with severe cramp like pains in the epigastrium, was intensely nauseated, and vomited violently The pain was accompanied by tenderness in the upper right quadrant of the abdomen, the maximum point being *in the region of the pylorus, the temperature rose to 102 F*, the pulse to 120, the blood count showed a slight leukocytosis, urination was frequent and painful, the urine showing albuminuria but not casts Despite gastric sedatives and lavage the nausea and vomiting persisted for ten hours The violent onset coupled with the pain and tenderness in the upper abdomen, suggested the possibility of a duodenal perforation However the low blood count, the lack of abdominal rigidity, and the peculiar intensity of the nausea pointed to some form of poisoning rather than to a perforation After the discontinuance of the scarlet red and the employment of repeated stomach and colonic washes the symptoms gradually subsided One week later the scarlet red was again applied to a small area, and gradually increased until two thirds of the circum

ference was covered The same toxic symptoms appeared, but of a milder degree, and again disappeared on the withdrawal of the scarlet red After a second interval of rest the scarlet ointment was applied in a 4 per cent strength, no further toxic symptoms developed Throughout the treatment there were no signs of local wound irritation Four months after admission to the hospital the patient was discharged cured

91 **Salvarsan in Leprosy**—In the case of four or five patients the administration of salvarsan by Wellman resulted in clinical improvement The other case ended fatally from the result of accidental burns before observations could be completed. Two cases in which the disease was least advanced showed the best results One of the controls remained unchanged in condition and the other grew steadily worse and finally died In one case, *Bacillus leprae* disappeared from the nasal secretion after treatment. Four patients showed partial or complete resolution of the specimen nodules examined after treatment

1 **High Blood Pressure.**—Of drugs says Osler, none are entirely satisfactory in chronic hypertension Nitrites in various forms may be used, and are often of temporary benefit, but he thinks the general opinion now is that neither the nitrites nor potassium iodid are of permanent benefit, though now and again one meets with an instance in which the prolonged use of potassium iodid is followed by marked lowering of the pressure A preparation of mistletoe has also been much lauded, but it, too, is very variable in its effects Osler advises caution in this point—if the patient does not feel so well, and begins to get thin and look badly, stop all drugs, trust to general measures and let the pressure rise In the robust man of full habit in the hypertensive crises with headaches, dyspnea or angina, a free venesection is indicated, to be followed by mercurial and saline purges

2 **Calculation of Drug Dosage for Children**—The method suggested by Dilling for the metric system $\frac{\text{Age} \times 5}{100}$, or for the imperial system $\frac{\text{Age}}{20}$ results in doses which correspond closely with those demanded by the average weights of nonadult individuals of both sexes at different ages Using 100 as the denominator and 20 as the adult age, thus, the formula $\frac{\text{Age} \times 5}{100}$ gives a curve which lies for the greater part of its course between the percentage weights of males and females Such a fraction is extremely easy to calculate when metric weights are in use Thus, if 0 33 gram be the adult dose the dose for a child of 7 is 0 1155 gram obtained by multiplying 0 33 by 35, and shifting the decimal points two places to the left

26 **Bacteriologic Examination of Urine**—The importance of a bacteriologic examination of the urine is emphasized by

White, and he cites a number of cases to prove the correctness of his contention He points out that the contamination of urine by microorganisms, even when it is withdrawn from the bladder with aseptic precautions, is not uncommon, and females are more affected than males, the right kidney is much more frequently implicated than the left, and *Bacillus coli* is by far the commonest microorganism Various treatments of the illness associated with *Bacillus coli* in the urine have been advised, and in estimating their value regard must be paid to the great variation in the severity of the cases and to the fact that some get well without any treatment The patient should certainly be put to bed and have plenty of fluid to drink Those who attach much importance to the state of the intestinal tract will if there are any symptoms that this is disordered, try to get into a healthy condition. Alkalies have been largely used, and some think with great benefit They are given because it is thought that *Bacillus coli* will not grow in an alkaline fluid, but in reality it will grow equally luxuriantly in either alkaline or acid urine White's usual treatment is to give plenty of hexamethylenamin, say, 10 grains dissolved in water four or five times a day for an adult, together with from 10 to 20 grains of acid sodium phosphate dissolved in water every hour the patient is awake so as to keep the urine acid, for hexamethylenamin acts by the liberation of formaldehyd He usually also uses an autogenous colon vaccine, giving an adult from 3,000,000 to 5,000,000 for the first dose, a second similar dose is given three days afterward, and later from 20,000,000 to 50,000,000 are given once a week Even with the most thorough treatment, it is often difficult or impossible to get rid of the microorganisms from the urine, but that seems to White the very reason why every means should be taken, and therefore he uses vaccines as well as urinary antiseptics Certainly patients benefit while on this treatment, although often the illness passes away, but the microorganisms remain in the urine When this is so it may be that the bacilli having changed their character, a fresh, autogenous vaccine is desirable, but, he says, we must have a much larger experience before we know whether a change of vaccine causes the bacilli to disappear more rapidly than they would if vaccines were discontinued altogether after the subsidence of symptoms

27 **Histology of Experimental Rheumatism**—The authors have attacked this problem afresh from the histologic point of view Do the rabbit lesions which follow inoculation with streptococci isolated from human rheumatism correspond microscopically with those of human rheumatism or not? Their results hitherto have been few, but such as they are they enable them to reply to this question in the affirmative Inoculation of rabbits with streptococci recovered from cases of rheumatic infection provoked arthritis, carditis and other lesions Histologic examination of these lesions discovered (*a*) that they are identical with similar changes provoked in rabbits by inoculation with a similar microorganism in the hands of other investigators, (*b*) that they include all the phenomena, even the submiliary *nodule, found* in the rheumatic lesions of man Such differences as exist between the experimental rheumatic infection and the human variety are accounted for by a difference in the mode of entry of the infective agent in the two conditions

28 **Injuries to Bones at Wrist.**—The analysis of 214 cases by Knox and Salmond has shown that the most common injury at the wrist in cases in which the epiphyses have joined their shafts is a transverse fracture one half inch above the lower end of the radial bone the lower fragment being displaced backward and with or without a fracture of the styloid process of the ulna, while in cases in which the epiphyses are not yet united, the commonest injury is a transverse fracture about 1 inch above the lower ends of both forearm bones and with both lower fragments displaced backward

38 **Treatment of Bronchitis**—As to the treatment of a stout patient suffering from acute bronchitis, Campbell says First of all, give him cool fresh air to breathe Next, order a tube of oxygen to be at hand Apply a dozen leeches over the liver and encourage the flow of blood by subsequent hot fomentations Order 5 gr of calomel and a mixture containing carbonate of ammonia and senega As for the edema, the most effective way of getting rid of it is by means of digitalis and theocin sodium acetate (5 gr *ter in die*) As regards food it should in all cases of this kind be practically withheld altogether for a few days at least Starve the patient Campbell says many lives are sacrificed through ignorance of this common sense precept Every particle of food which is absorbed goes to increase the *production of carbonic acid, and it is the* excess of this in the blood which causes the dyspnea The patient may drink as much water as he likes, or he may have weak tea

As to the treatment of chronic bronchitis in an obese subject The air the patient breathes shall be as pure as possible, and endeavor should be made to bring about a vigorous circulation of healthy blood throughout the body As regards climate, a pure, dry, warm air is the best Cold air is not in itself bad for the lungs, it has rather a stimulating effect The injurious effect of cold climate, especially a cold damp climate, on the respiratory mucous membrane depends on its unfavorable effect on the skin The skin excretes less actively in a *cold damp than in a warm dry climate The respiratory* mucous membrane and the skin are to some extent complementary to one another, and if the action of the skin is checked, much of the poisonous material which is normally eliminated by it is got rid of by the respiratory membrane, which in this way may be irritated into inflammation The bronchitic therefore does best in a warm, dry climate

The promotion of a vigorous circulation of healthy blood is secured by common sense means Get the patient down to his normal weight Have recourse to diabetic diet and prescribe a due amount of exercise The withdrawal of starch and sugar is often followed by a considerable improvement in digestion and a reduction in the generation of poisons which by *their absorption into the blood* exercise *so injurious an* effect on the bronchial mucous membrane Such starch as is allowed should be chewed very thoroughly, so as to secure, as far as possible, its predigestion in the buccal cavity In this way much of it may be converted into dextrins, and some of it even into maltose, before it reaches the stomach A favorite plan of Campbell's is to order the patient a grain of grey powder and a teaspoonful of castor oil (in the form of a tasteless emulsion) every night for some months or, instead of the oil we may find it better to give half an ounce to 1 ounce of paraffin As regards expectorants, alkalies and ether are probably the best The part of expectorants in the treatment of bronchitis is, however, a subsidiary one Too great reliance has been placed on them in the past to the neglect of common sense measures Bronchitis has never been cured by drugs, any more than dyspepsia has, but it often yields to common sense treatment, and no variety more so than the chronic bronchitis of the elderly stout person Campbell believes that there is a danger that as we become more scientific we may neglect the more prosaic dictates of common sense.

49 **"Penny Signs" in Pleurisy and Ascites**—Many years ago Professor Pitres of Bordeaux called attention to a new sign in pleurisy with effusion based on the transmission of the sound obtained by tapping one coin on another, which he called the "*signe du sou*" Brelet says that Pitres' sign is often of the greatest assistance in the diagnosis of pleural effusion, often a matter of some delicacy To elicit Pitres' sign in a case of pleurisy with effusion, a coin is placed flat on the chest, in front, just below the nipple, and an assistant taps it with another coin, striking vertically While this is being done the observer listens over the back and side of the thorax If the interior of the thoracic cavity be occupied by a homogeneous medium, either solid or liquid, which conducts sound more perfectly than normal pulmonary tissue, the percussion sound is audible as a clear ringing silvery vibration The "penny sign" is, therefore, not pathognomonic of pleural effusion, but as massive indurations of the pulmonary parenchyma are much more uncommon than pleural effusions this sign taken in conjunction with the more or less complete series of other signs and symptoms, will, in most instances, indicate the existence of a liquid effusion into the pleural cavity In a normal abdomen the "penny sign" is negative In obesity the penny sign is always negative, one gets a sound like that of bronze In meteorism and tympanism the results are the same In ascites, of which the author gives thirty five instances, the result in thirty one cases was very obviously positive that is to say, he heard a clear, silvery sound In four cases it was doubtful or faintly positive It follows therefore that when there is a mass of fluid between the two points the transmitted sound is clear and silvery in tone With regard to the cases in which the result was doubtful it is to be noted that in one of them the ascites was very abundant and under great pressure so that possibly the heightened tension hindered the transmission of the sound In the other instances it may be that peritoneal adhesions fixed the loops of the intestine, locking up the effusion into compartments and thus interfering with the production of the "penny sign" In most of these cases it was found possible, by shifting the point of percussion and auscultation, to demonstrate the limits of the effusion

55 **Carcinoma of Breast**—Ross firmly believes that as the precancerous stage of cancer is inflammatory, all breasts affected with chronic mastitis after the patient has reached fifty years should be removed No breast tumor should be regarded as simple until it has been proved so by microscopic examination The sooner we cease to worship the age incidence of malignant disease as a fetish the better it will be for the patient and the reputation of surgery The sooner we recognize that the extensive wounds of breast amputations should be closed and not necessarily drained, the less frequently we shall hear of "recurrence" in the scar Merely to dissect away the pectoralis fascia when operating for breast cancer is to court disaster When operating on cases of cancer of the breast we must be prepared for an extensive and tedious dissection, otherwise we had better leave the case alone In every case, however small the primary growth may be, we must remove the breast open the axilla and clear away all glands and fat, and remove the pectoralis major, if we have the least doubt about the state of affairs around the coracoid process we should also remove the pectoralis minor Finally hemostasis must be complete and drainage of the wound is to be avoided

Indian Medical Gazette, Calcutta

64 *Treatment of Snake-Bite by Permanganate of Potassium W B Bannerman
65 Extraction of Cataract in Its Capsule by Division of Suspensory Ligament. V B Nesfield
66 *Special Type of Recurrent Fever Due to a Spirocheta C A Browse
67 Gleanings from Calcutta Post Mortem Records. L. Rogers

64 **Treatment of Snake Bite.**—The conclusions reached by Bannerman as to the action of potassium permanganate powder on small doses of cobra venom injected just under the skin appear to be that this treatment is of some little use under these highly artificial conditions It must be remembered, however, he says, that a snake does not deposit its venom under the skin, but striking as it does with its fangs at right angles to the skin the poison must usually be placed well below the fascia of the part, and therefore further removed from the application of a chemical antidote With regard to Daboia venom injected just under the skin, the results are very similar to those obtained with the venom of the cobra, *i e*, that under artificial conditions the treatment by free incision and rubbing with powder of potassium permanganate is of some little use As a practical measure for employment after actual snake bite it appears to be of no use whatever

66 **Recurrent Fever**—Browse calls attention to a disease observed in Quetta which appears to differ in many respects from the classical forms of recurrent fever at present described and which at the same time has certain characteristics common to each The disease is caused by a spirochete It differs from classical recurrent fever in the type of pyrexia, and the blood changes, namely, the slightly marked polymorphonuclear increase and distinct large mononuclear increase, it resembles classical recurrent fever in some of its clinical features It differs from African tick fever chiefly in the very great contrast in climatic conditions under which it develops In other respects, such as the type of pyrexia and blood changes, there is a decided resemblance The clinical features of the disease are not very distinctive, and to a modified extent resemble those which occur in relapsing fever It is a mild disease, and in no case were there, at any time, symptoms of a serious or alarming nature In most the only symptoms were those common to any febrile condition In the eighteen cases seen by Browse the onset was sudden, with a feeling of cold but no actual rigor Vomiting was the exception and in no case was jaundice or rash noticed All the patients invariably felt perfectly well directly the fever ceased and much resented being detained in hospital A few after late relapses, became anemic and debilitated otherwise the disease was trivial in its effects Pains in the limbs and joints were not uncommon but were only marked in three cases out of eighteen Eight patients had enlargement of the spleen on admission, but of these, five were men with chronic splenitis not due to the spirochetes Pain and tenderness over the spleen and liver during the fever paroxysms was observed in three cases, but was the exception The temperature follows a course similar to that of African tick fever, as it attacks the foreigner to the country In no case did the temperature remain constantly elevated for as long as four days as it does in relapsing fever

Annales de Gynécologie et d'Obstétrique, Paris

October XXXIX No 10, pp 577 640

68 *Prophylaxis of Operative Infect um I Lecène Commenced in No 9
69 *The Urea Index in Pregnancy la femme enceinte) Le

68 **Prophylaxis of Wound Infection in Gynecology**—Lecène looks to improved technical skill in operating for prevention of operative infection, the use of gloves, asepsis and limitation of the field of operation, exact peritonization of all raw surfaces, with or without the roofing over of the small pelvis, and a more skilful selection of the methods to be applied in the individual cases Progress will be along the lines of stricter asepsis and closer adherence to physiologic processes

69 **Urea Index in Pregnancy**—Ambard's formula for estimating the "uremic constant" in individual cases was described in THE JOURNAL, September 7, p 818, and July 20, p 229 Le Lorier has determined this index in twenty four pregnant women, in ten the index was within normal range, in four much below and in four much above In one in the latter group the index was 0 850 (the normal average is 0 065), and it thus indicated defective elimination on the part of the kidneys The patient was a primipara of 24 at the eighth month who had three eclamptic convulsions three weeks before but none since The Esbach test showed still considerable albuminuria The second patient in this group had an urea index of 0 106 and there was considerable albuminuria due in part to infection of the bladder The third patient had an index of 0 104 and although the urine seemed normal yet the woman required strict dietetic measures to bring her safely to term The fourth patient had an index of 0 896, she was in coma at the time and died the next day The details of the twenty four cases are tabulated for comparison They demonstrate anew that the proportion of urea in the blood serum is not a reliable criterion alone for determination of the degree of permeability of the kidneys

Bulletin de l'Académie de Médecine, Paris

October 15 LXXVI No 34 pp 247 276

70 *Influence of Chemical Composition of Air on Vitality of Microbes A Trillat and Guéniot
71 *Direct Sunlight in Treatment of Surgical Tuberculosis, etc (Héliothérapie) A Poncet and R Leriche

70 **Influence of Contamination of Air on Microbes**—The extensive researches reported demonstrate that vitiation of the air by the emanations of putrefaction favor the vitality of microbes, and that certain gases in water have the same favorable action, such gases as are alkaline in nature and contain ammonia, fatty amins and volatile nitrogenized substances allied to the alkaloids It was found that distilled water containing one five millionth of its weight of a putrid gas and an infinitesimal amount of mineral matters serves as a fine culture medium when inoculated with germs, they grow luxuriantly in it The experiments related confirm anew the deleterious influence of fogs, extreme humidity, low atmospheric pressure, vicinity of a focus of putrefaction or contamination with the gases of respiration They throw light further on the changes in food noticed during storms and other unusual atmospheric conditions and the aggravation of unprotected wounds

71 **Direct Sunlight in Treatment of Local Processes**—Poncet has been utilizing for twenty years and in over three hundred cases the benefits from direct exposure of local tuberculous and other processes to the sunlight He commenced this long before "heliotherapy" was heard of His experience has shown that the method is applicable in nearly every climate and that scrofula, rachitis and all forms of inflammatory tuberculosis seem to do better at the seashore, while deep bone processes and any tendency to pulmonary tuberculosis indicate the mountains rather than the seashore The exposures should not be over ten minutes at first, gradually increasing until the part is exposed to the direct sunlight for three hours morning and afternoon One of his most successful cases was in a patient who got his exposures on the fifth floor of a tenement house in the center of Lyons The heliotherapy does wonders, he says, in tuberculous peritonitis and as an adjuvant to operative measures in nearly all forms of tuberculosis, in tardy consolidation of fractures, and for all torpid, chronic infectious processes and trophic disturbances Even when a plaster cast is necessary, he always applies it in such a way as to permit exposure to the direct sunlight The benefit is most marked, as a rule, with patients who "burn" most readily

Archives des Maladies du Cœur, Etc, Paris

October, V No 10, pp 625 688

72 *Pathogenesis and Pathologic Anatomy of Chronic Aortitis and Atheroma in Children A L Franckel
73 *Angina Pectoris and Tobacco G Mouriquand and L Bouchut
74 Case of Sporadic Hemophilia with Fatal Anemia E de Massary and P V Rodot

72 **Aortic Disease in Children.**—Franckel summarizes thirty four cases, including seven from his own experience and one reported by Wilson and Marcy in THE JOURNAL, 1907

73 **Angina Pectoris and Tobacco**—In the case reported a man of 34, a great smoker, developed attacks of angina pectoris and died in one. There was no trace of venereal disease or alcoholism, but signs of tobacco poisoning had been pronounced during life and the man had spontaneously reduced his daily ration of cigars and cigarets as he had noticed that too much smoking aggravated the dyspnea He died five months after the first signs of heart trouble The case would have been cited as one of fatal tobacco poisoning but necropsy revealed syphilitic lesions in the aorta partly closing up the openings into the coronary arteries There is no evidence to date that tobacco alone can induce fatal angina pectoris, but of course it can aggravate an existing tendency

76 *Surgical Treatment of Uterine Hemorrhage P Bar
77 Evolution of the Mammary Gland (La glande mammaire Les phases qu elle présente au cours de son évolution et de leur déterminisme d après les recherches de MM Bouin et Ancel.) J L Chirié.
78 *Tuberculosis of Uterine Cervix B Desplas

75 **Cancer of the Uterine Cervix.**—Faure states that his oldest cured patient was operated on over fourteen years ago, and he has remained faithful ever since to the method of removing the entire uterus and part of the vagina in a single mass He has now an experience of 250 such operations, and advocates ligating the hypogastric arteries, mentioning several other useful points in technic Radium applications are valuable after removal of the tumor but he warns expressly against the use of radium preliminary to an operation Any advantage from it is far outbalanced by the sclerosis of adjacent tissues which it induces, hampering the work on the ureters in particular But he commends in high terms the application of radium three weeks after the operation, introducing it into the funnel left by the excision of the cervix

76 **Operative Treatment of Uterine Hemorrhage**—Bar analyzes the 153 cases of excessive hemorrhage during pregnancy or childbirth at the maternity in his charge since 1897, in a total material of 20,000 obstetric cases With hemorrhage from an abnormally implanted placenta, only 2 6 per cent of the women succumbed to the hemorrhage while 6.5 per cent died of infection for which obstetric procedures were probably responsible No less than 31 37 per cent of the 153 women presented symptoms of infection Three of the women died from secondary hemorrhage caused during the extraction of the fetus The danger therefore with an abnormally inserted placenta is mainly from infection and from new hemorrhage caused by maneuvers to hasten delivery Laceration of the cervix from rapid dilatation seems to be particularly dangerous in this respect the possibly minute hemorrhage from the laceration proving the last straw

78 **Tuberculosis of Uterine Cervix.**—Desplas reviews the extensive monographs that have appeared on this subject of recent years and emphasizes the importance of traumatism, anomalies in menstruation and defective development of the genital system as contributing factors The main point in the diagnosis is to think of the possibility of tuberculous lesions at this point, and then to differentiate them by exclusion If primary lesions here prove rebellious to local treatment iodin, silver nitrate, the actual cautery, interstitial injection of zinc chlorid or Bier's method of vacuum hyperemia, the cervix should be amputated or the entire uterus removed.

Abdominal hysterectomy is advocated by many in case there is suspicion that the adnexa are involved

October 29 Supplementary No, pp 885 900

82 *Fibromas in Nasopharynx. J and L Ducuing

81 **Treatment of Tardy Pains in the Stomach**—Meunier has been impressed with the resemblance between the symptoms presented by a minute ulceration near the pylorus duodenum junction and fissure of the anus The tardy pains are the result of morbid contracture of the sphincter, and this may also be the primal factor in the development of the ulceration The logical conclusion is that the lesion and pain may be amenable to the same treatment which has proved its efficacy with fissure of the anus, namely, forcible dilatation of the sphincter He gives an illustration of the small inflatable ball he uses for the purpose, connected by a long tube with a rubber bulb The little ball is swallowed by the patient as he drinks a glass of some alkaline beverage The ball is left undisturbed for some hours, possibly over night, to make sure that it has passed into the duodenum It is then inflated and is gently pulled upward The resistance offered by the pylorus is felt distinctly when the ball reaches a point about 55 cm from the teeth The procedure is repeated every two or three days, inflating the ball more and more each time but never enough to cause pain After five or six applications of the measure the tardy pains became attenuated, as a rule, if they persisted after this he advised operative measures, but he thinks that this mechanical dilatation should be given a trial before advocating an operation

85 *The Atropin Test in Diagnosis of Brain and Meningeal Disease (L'épreuve de l'atropine dans le diagnostic des états méningés et cérébraux) M Roch and F Cottin

85 **The Atropin Reaction**—Roch and Cottin declare that while the atropin reaction in cases of bradycardia cannot be relied on absolutely, yet it furnishes valuable presumptive evidence, and as it is so harmless and within the reach of every practitioner it deserves wider application It is invariably positive in the cases of bradycardia of nervous cerebral origin and negative with bradycardia from heart block Bradycardia due to auto-intoxication is never so pronounced as when a definite brain lesion is involved The test is merely the subcutaneous injection of 0 002 gm of atropin sulphate and control of the heart beat afterward The heart beat is not modified by the drug in case of actual heart disease while the pulse is accelerated when the myocardium is sound The atropin has a paralyzing action on the vagus terminals in the heart The reaction becomes evident in fifteen minutes and reaches its maximum in about an hour The only by effect is possibly a little dryness of the throat Experiences with the test in Bard's service have shown that an abnormally slow pulse can be whipped up by the atropin when it is of extracardiac origin and thus may turn the scale in favor of the diagnosis of meningitis or brain tumor in dubious cases Intracranial pressure on the nerve centers in these cases is causing the bradycardia and the atropin counteracts this. In a recent case the symptoms suggested meningitis eight months after infection with syphilis The pulse was very slow but after injection of atropin it rose from 40 to 100 and then gradually dropped back to 60 Under antisyphilitic treatment recovery was soon complete The atropin reaction was equally marked in a case of meningitis following trauma of the head, the heart beat rising from 55 to 125 under the atropin A number of typical cases are related in which the diagnosis was suggested by the atropin reaction when the symptoms seemed to indicate typhoid One young man had fever, chills, vague headache, enlarged spleen and agglutination reaction with a tendency to stupor, pulse only 52 The cerebrospinal fluid seemed normal but the atropin test was applied after several days of uncertainty and the pulse climbed to 120 in an hour The diagnosis of meningitis was thus possible several days before other symptoms of the general purulent meningitis developed In another case a robust man of 50 developed violent headache accompanied by bradycardia but no fever, Wassermann and eye findings were negative, the spinal fluid was limpid and the atropin reaction pronounced He died from intercurrent pneumonia five days later, and necropsy revealed a chronic pachymeningitis with adhesions and hyperemia In another case the symptoms pointed to heart disease and the bradycardia observed was ascribed to this until the positive atropin reaction compelled reexamination of the patient when other symptoms were discovered previously unheeded, indicating cerebellar disease In another series of cases the negative reaction excluded extracardiac factors and permitted effectual treatment [Talley discussed the prognostic significance of the atropin reaction in heart disease in the *Am Jour Med Sci*, 1912 cxliv, 514, abstracted in these columns recently, p 1485]

133 Reporting of Industrial Disease (Anmeldung von Gewerbekrankheiten) F Koelsch

123 **Extraperitoneal Cesarean Section**—Küstner has had this operation done in seventy two cases in his maternity, and regards it as a very valuable method for delivering the child when the smallness of the pelvis or other reason renders it improbable that the child can be spontaneously expelled without injury to it None of the mothers succumbed except one from a chloroform accident, and only four of the children died, one from an eclamptic mother and three which were so deeply asphyxiated that it proved impossible to reanimate them It is immaterial with this technic whether there is infection or not, so it can be applied in cases in which without it there can be question only of craniotomy

124 **Occult Cholecystitis**—Bahrdt refers to cases of cholecystitis in which the fever comes on with symptoms only on the part of the lungs and bronchi The first sign of trouble is fever which may run high for a day or so, and râles are found in the lower part of one lung, with slight dulness and signs of mild bronchitis Then the fever subsides and with it the symptoms in the respiratory apparatus They return at a new attack, but there are no sounds of friction in the pleura The patients seem very ill during the attacks but nothing can be found to explain them at first except the slight and inadequate local bronchitis and infiltration of the lung Then suddenly slight jaundice is noticed, generally during or after an attack of fever, and it soon subsides The next attack may be ushered in with a chill, the bronchial findings return and with them the slight jaundice, and this time there may be local pain and tenderness in the gall bladder region One patient passed a hard gall stone after sixteen such attacks and there has been no recurrence of any of the symptoms on the part of either the respiratory or biliary apparatus during the seven years since Pneumonia is sometimes accompanied by cholangitis, but here the condition is reversed, the lungs and bronchi are secondarily affected The germs must be comparatively avirulent in such cases as they are conquered each time by the local defensive forces. This assumption is sustained by the absence of suppuration, no abscess was found even in a case in which attacks of fever up to 104 F had returned at intervals for years In one of his four cases the right lung was exclusively affected during the sixteen attacks, but in the others both sides were involved, always the lower lobe One patient was a man of 87 who for ten months had one or two of these attacks of fever for one or more days each month, with signs of bronchitis and later slight jaundice and finally pains in the liver region but no gall stones were passed The man died then of intercurrent pneumonia This was responsible also for the death of another patient, a robust woman of 79 with arteriosclerosis In 1903 she had a day of high fever and bronchitis, returning at brief intervals during two months and then with longer intervals, accompanied later by jaundice and exacerbation of the bronchitis which became chronic Necropsy revealed a large gall stone in the dilated common bile duct, but no abscess In the fourth case the man had chronic eczema and the jaundice and tenderness in the liver region developed at his second attack within one month After four or five attacks there were no more for six years, when the febrile bronchitis returned, jaundice and gall stone colic coming on the fourth day cleared up the diagnosis Treatment should aim to promote the flow of bile and cholesterin metabolism and to sterilize the intestines, possibly with naphthalin, if the patient can bear it

125 **By Effects with Neosalvarsan.**—Simon reports two cases in which the neosalvarsan caused severe angioneurotic symptoms, collapse, congestion or acute swelling of the brain, with an exanthem The latter patient had complained of headache and the pupils did not react alike, before the drug had been given Two days after the second injection of neosalvarsan he became unconscious for five hours and had violent headache on rousing Busse reports the death of a girl of 18 after two injections of neosalvarsan, and necropsy revealed the changes characteristic of salvarsan and neosalvarsan intoxication He declares that these fatalities are not due to any fault in technic but to the treacherous action of arsenic, which can never be foreseen in the individual case This danger inheres in the new preparations of arsenic just as in the old classic preparations, and the physician must reckon with the possibility of encountering it when he uses large doses of any one of them The only symptom presented by Busse's patient was the recurrence of nodules on the external genitals during the last eight months, the two injections of 0 6 neosalvarsan were given intravenously with an interval of eight days Serious symptoms developed the day after the second injection, with death two days later

130 **Treatment of Epistaxis**—Ritschl calls attention to the prompt arrest of epistaxis by Nägeli's method of pulling on the nerves and vessels in the neck—the so called *Kopfstützgriff* and *Kopfstreckgriff* The stretching of the cervical sympathetic stimulates the vasoconstrictors, and thus acts on the epistaxis Standing behind the seated patient, place your hands under the angle of the jaw and the sides of the back of the head and try to lift the head up The head can be drawn a little backward at the same time which permits the blood to escape into the nasopharynx Ritschl has found this simple measure invariably successful in arresting epistaxis in one or two minutes at most Nägeli has called attention to a number of these mechanical measures as a means to combat neuralgia and neuroses

CLINICAL FEATURES OF SUDDEN OBSTRUCTION OF THE CORONARY ARTERIES

JAMES B HERRICK, M D
CHICAGO

Obstruction of a coronary artery or of any of its large branches has long been regarded as a serious accident Several events contributed toward the prevalence of the view that this condition was almost always suddenly fatal Parry's writings on angina pectoris and its relation to coronary disease, Jenner's observations on the same condition centering about John Hunter's case, Thorvaldsen's tragic death in the theater in Copenhagen with the finding of a plugged coronary, sharply attracted attention to the relation between the coronary and sudden death In Germany Cohnheim supported the views of Hyrtl and Henle as to lack of considerable anastomosis, and as late as 1881 lent the influence of his name to the doctrine that the coronary arteries were end-arteries His Leipsic necropsy experience, as well as experiments on dogs, forced him to conclude that the sudden occlusion of one of these vessels or of one of the larger branches, such as the ramus descendens of the left coronary, meant death within a few minutes Others emphasized the same view

No one at all familiar with the clinical, pathologic or experimental features of cardiac disease can question the importance of the coronaries The influence of sclerosis of these vessels in the way of producing anemic necrosis and fibrosis of the myocardium, with such possible results as aneurysm, rupture or dilatation of the heart, is well known So also is the relation of the coronaries to many cases of angina pectoris, and to cardiac disturbances rather indefinitely classed as chronic myocarditis, cardiac irregularities, etc It must be admitted, also that the reputation of the descending branch of the left coronary as the artery of sudden death is not undeserved

But there are reasons for believing that even large branches of the coronary arteries may be occluded — at times acutely occluded—without resulting death, at least without death in the immediate future Even the main trunk may at times be obstructed and the patient live It is the object of this paper to present a few facts *along this line, and particularly to describe some of the* clinical *manifestations of sudden yet not immediately* fatal cases of coronary *obstruction*

fact that presenting the clinical features of coronary
the patchy fit may be well to consider certain facts
at autopsy make that sudden obstruction is not neces-
sclerotic vessels uch proof is afforded by a study of the
ormal as well as of the diseased heart,
t and by bedside experience

The coronaries are not so strictly end-arteries, i e, with merely capillary anastomoses, as Cohnheim and others thought By careful dissections, by injection of one artery from another, by skiagraphs of injected arteries and by direct inspection of hearts made translucent by special methods, there is proof of an anatomic anastomosis that is by no means negligible

Jamin and Merkel's† beautiful stereoscopic skiagrams show the remarkably rich blood-supply of the heart, with occasional anastomoses between vessels of considerable size The possibility of injection of one coronary artery from the other is admitted even by those who deny that such injection proves more than a capillary non-functioning anastomosis Amenomiya,[1] by injecting hearts of young persons, showed naked-eye anastomoses in the subepicardial tissue He feels that Hirsch and Spalteholz[2] have nearly cleared up the question as to the relation between the heart muscle and disease of the coronary artery from the anatomic standpoint Hirsch says that in dogs the anastomosing vessels are functionally competent, and Spalteholz says that in man the vessels are nearly the same as in dogs, rich in anastomoses even in those of considerable caliber The latter investigator, by a method of injection and treatment of the heart so as to make the muscle transparent, shows to the naked eye that there are anastomoses of considerable size

Among others who are on record as believing that there are non-negligible anastomoses may be mentioned Haller, Huchard, Orth, Michaelis, Langer, Legg, West All recognize, however, that there are individual differences, and also that though the heart may show rich anastomoses, these are not necessarily functional, i e, that an artery which anatomically is not a terminal artery may yet be such functionally

But there is proof not only of anatomic connection between the two coronaries, but that in certain instances, at least, such connection is of functional value Experiments on lower animals and the clinical experiment of disease of the coronaries with autopsy findings show this

Much of the earlier experimental work on the lower animals, obstructing the coronary arteries by ligatures, clamps or artificial emboli, *gave promptly fatal result* Among those who worked along this line and reached these conclusions may be mentioned Erichsen (1842), Panum (1862), *von Bezold, Samuelson (1880),* Cohn-

Deutsch. med Wchn

heim and Schulthess-Rechberg (1881), G Sée, Rochefontaine and Roussy (1881) Bettelheim (1892), Kronecker, and, to some extent, Michaelis The work of Cohnheim[3] attracted particular attention and his conclusions as to end-arteries, irreparable injury, and cessation of the beat of both sides of the heart within two minutes from the time of shutting off the coronary circulation confirmed and elaborated the conclusions of the earlier experimenters, and was in turn confirmed by the French writers just named, by Bettelheim and others

But soon dissent was heard from various quarters as to many of Cohnheim's results, and among other things as to the sudden death following the ligations Michaelis found that the injury from ligation in rabbits was not so serious or irreparable as in dogs Fenoglio and Drouguell, in 1888, found that some dogs might live Porter showed that after ligation of one or two large branches of the coronary artery a dog might live hours or days More than half his animals lived after ligation of the descending branch of the left coronary Von Frey, at the Congress for Internal Medicine in 1891, said that he doubted the sudden stopping of the heart as Cohnheim taught he believed that clearly the greater weight should attach to those observations in which the ligation was borne without harm, and that the stopping of the heart was not a necessary consequence of the obstruction of a large coronary branch Hirsch in eight dogs and two apes had no sudden deaths from ligation Bickel,[4] under Orth and Amenomiya, had a dog live nineteen days after the ligation of the descending branch of the left coronary, he killed two dogs, one on the eighth and the other on the seventeenth day after ligation Kolster ligated smaller branches, his dogs lived, and when killed at intervals of several weeks showed the progressive changes of fibrosis of the myocardium Imperfect technic, by which damage was done to the heart muscle and pneumothorax produced, is offered as a partial explanation, at least, for the more rapidly fatal results obtained by Cohnheim and others Miller and Matthews[5] call attention to the better results where ether as an anesthetic is employed rather than curare or other drug With ether they were able to ligate large branches, many of their dogs living several weeks

Experimentally, then, sudden death, even late death, is not a necessary consequence of obstruction of even large branches, such as the descending branch of a coronary artery

There are numerous autopsy observations, frequently with helpful clinical history, that show directly or by inference the existence of efficient anastomoses, and the ability of the heart at times to survive the obstruction of a coronary or some large branch Some of these instructive cases may be mentioned Pagenstecher, on account of an accident, ligated the descending branch of the left coronary artery and the patient lived five days Thorel has seen hearts with complete obstruction of the artery, with fibrous or calcified myocardium, and yet no symptoms during life the patient dying of some other disease I have seen the descending branch completely occluded with an extensive fibrous area in the interventricular septum and at the apex, the latter aneurysmally dilated, where the process was clearly one of long standing West[6] cites several cases in which at autopsy complete obstruction of one coronary was found, yet the patients had long survived this serious lesion Chiari, in a 32-year-old nephritic, found a sclerosed right coronary plugged by a thrombus, with resulting scattered patches of myomalacia cordis in the areas supplied by this artery A portion of this thrombus had become detached and had embolically plugged the left coronary, resulting in sudden death From the symptoms and the autopsy findings the thrombus in the right artery had formed at least two days before The fact that the softened patches in the myocardium were scattered, with normal tissue between, and that the heart functionated fairly well until the left artery also was obstructed, leads Chiari to infer that anastomoses must exist between the right and left coronaries Merkel[7] drew the same inference as to anastomoses from the patchy character of the lesions in the heart of a woman of 76 years, there being normal muscle between the softened areas The left coronary was the seat of the obstruction He also saw in a man of 37 the left coronary closed, with nourishment through the right artery Dock[8] in a case of gradual occlusion of the right coronary artery was able to demonstrate a direct opening of the finer branches of the left coronary into the end of the right

Spalteholz says that we all know cases of stoppage of large vessels without large infarcts resulting Recklinghausen and Fujinami found this condition in man, as Hirsch had in dogs and monkeys, i e, smaller infarcts than the distribution of the vessel would lead one to expect Galli saw complete closure of the entrance to the right coronary artery yet no change in the myocardium By injection he found a round-about anastomosis between the right and left coronary arteries Samuelson cites the case of a patient living five hours after obstruction, Huber one of a patient living several days Aschoff and Tawara[9] saw a patient live fourteen days, "with nearly complete infarction of the parietal wall of the left ventricle" In several cases of angina pectoris cited by Huchard[10] the patients lived many hours after the onset of the final attack, which autopsy showed was due to a thrombotic closure of an artery Osler refers to the fact that the patient may live for some time after obstruction Krehl expressly states that in man the more or less sudden occlusion of an entire coronary artery, or at least a large branch, such as the descending branch, is compatible with a continuance of life

One may conclude, therefore, from a consideration of the clinical histories of numerous cases in which there has been careful autopsy control, from animal experiments and from anatomic study, that there is no inherent reason why the stoppage of a large branch of a coronary artery, or even of a main trunk, must of necessity cause sudden death Rather may it be concluded that while sudden death often does occur, yet at times it is postponed for several hours or even days, and in some instances a complete, i e, functionally complete recovery ensues

The clinical manifestations of coronary obstruction will evidently vary greatly, depending on the size, location and number of vessels occluded The symptoms and

end-results must also be influenced by blood-pressure, by the condition of the myocardium not immediately affected by the obstruction, and by the ability of the remaining vessels properly to carry on their work, as determined by their health or disease. No simple picture of the condition can, therefore, be drawn. All attempts at dividing these clinical manifestations into groups must be artificial and more or less imperfect. Yet such an attempt is not without value, as it enables one the better to understand the gravity of an obstructive accident, to differentiate it from other conditions presenting somewhat similar symptoms, and to employ a more rational therapy that may, to a slight extent at least, be more efficient.

The variations in the results are to be accounted for in part by variations in the freedom with which anastomosing branches occur. Presumably, too, symptoms will vary with the vessel or branches occluded. It is conceivable that with occlusion of the right coronary the symptoms might be different from those following obstruction of the left artery, systemic edema might be a consequence of the former condition and pulmonary edema of the latter. These points are, however, by no means settled either by experimental or clinical observation. The condition of the remaining vessels as to patency and presence of sclerosis must play an important part in deciding how much they are capable of doing in the way of compensatory nutrition to the anemic myocardium, the strength of the heart itself, as determined, perhaps, by old valvular or myocardial disease, would also have its influence. And presumably a sudden overwhelming obstruction, with comparatively normal vessels, would be followed by a profounder shock than the gradual narrowing [illegible] lumen through sclerosis which has accustomed the [illegible] to this pathologic condition and has perhaps ca[illegible] collateral circulation through neighboring or anast[illegible] vessels to be compensatorily increased. The [illegible] of the vessels of Thebesius is also not to be [illegible] in this connection, compensatory circulation [illegible] these accessory channels may be of considerable [illegible] in nourishing areas of heart muscle poorly [illegible] by sclerotic or obstructed arteries.

Attempts to group the [illegible] of coronary obstruction according to clinical [illegible] must be more or less unsatisfactory, yet, imper[illegible] the groups are, the cases may be roughly classified [illegible]

One group will include [illegible] in which death is sudden, seemingly [illegible] and perhaps painless. Krehl[11] has emphasized the [illegible] of the sudden death of this type, the [illegible] terminal respiratory agony, of distortion of the [illegible], of muscular contractions.

A second group includes [illegible] cases in which the attack is anginal, the pain [illegible] the shock profound and death follows in a few [illegible] several minutes at the most.

In a third group may be [illegible]-fatal cases with mild symptoms. Slight angina [illegible] without the ordinary causes (such as walking, [illegible] some of the stitch pains in the precordia, may [illegible] due to obstruction of small coronary twigs. Such [illegible] of these phenomena is, however only a [illegible] based on the fact that other causes for the pains [illegible] and that the patchy fibrosis of the myocard[illegible] later found at autopsy may have originated [illegible] of the sclerotic vessels, and such [illegible] small vessels may well have produced symptoms differing chiefly in degree from those caused by obstruction of larger arteries of the heart.

In a fourth group are the cases in which the symptoms are severe, are distinctive enough to enable them to be recognized as cardiac, and in which the accident is usually fatal, but not immediately, and perhaps not necessarily so. It is to the clinical features of this group that attention is directed in what follows.

By way of introduction, I give in outline the history of a case, experience with which acutely attracted my attention to this subject.

Case 1.—*History*.—A man, aged 55, supposedly in good health, was seized an hour after a moderately full meal with severe pain in the lower precordial region. He was nauseated and believing that something he had just eaten had disagreed with him he induced vomiting by tickling his throat. The pain continued, however, and his physician was called, who found him cold, nauseated, with small rapid pulse, and suffering extreme pain. The stomach was washed out and morphin given hypodermically. The pain did not cease until three hours had passed. From this time the patient remained in bed, free from pain, but the pulse continued rapid and small, and numerous râles appeared in the chest. When I saw him twelve hours from the painful attack his mind was clear and calm, a moderate cyanosis and a mild dyspnea, were present. The chest was full of fine and coarse moist râles; there was a running, feeble pulse of 140. The heart tones were very faint and there was a most startling and confusing hyperresonance over the chest, the area of heart dulness being entirely obscured. The abdomen was tympanitic. The urine was scanty, of high specific gravity, and contained a small amount of albumin and a few casts. The temperature was subnormal, later going to 99 F. Occasionally there was nausea and twice a sudden projectile vomiting of considerable fluid material. This condition remained with slight variations up to the time of death, fifty-two hours after the onset of the pain, though at one time the râles seemed nearly to have disappeared. A few hours before death the patient described a slight pain in the heart region, but said it did not amount to much. A remarkable circumstance, and one that occasioned surprise in those who saw the patient and who realized from the almost imperceptible pulse and the feeble heart tones how weak the heart must be, was the fact that he frequently indulged in active muscular effort without evident harm. He rolled vigorously from side to side in the bed, sat suddenly bolt upright, or reached out to take things from the table near by, and once, feeling a sudden nausea, he jumped out of bed, dodged the nurse and ran into the bathroom, where he vomited, and yet he seemed none the worse for these exertions.

Necropsy (Dr. Hektoen).—The heart was of normal size, but both coronary arteries were markedly sclerotic, with calcareous districts and narrowing of the lumen. A short distance from its origin the left coronary artery was completely obliterated by a red thrombus that had formed at a point of great narrowing. The wall of the left ventricle showed well marked areas of yellowish and reddish softening, especially extensive in the interventricular septum. At the very apex the muscle was decidedly softer than elsewhere. The beginning of the aorta showed a few yellowish spots, these areas becoming less marked as the descending part was reached. An acute fibrinous pericardial deposit, which showed no bacteria in smears, was found over the left ventricle. (The pericarditis probably explains the slighter pain complained of a few hours before death.) There was marked edema of the lungs. In other respects the anatomic findings were those of health.

A colleague personally related to me the case of a man of 60 who, three days after a severe anginal seizure fe[illegible] well enough to walk on the street though [illegible] dyspnea. He died suddenly on the fif[illegible] obstruction in the left coronary, and the ation of the pain to the neck and arm, the diagnosis will not be so difficult as where these suggestive aids are lacking The bilateral character of the emphysema, the persistence of breath sounds, often with râles, the failure of the heart to be dislocated, will help exclude pneumothorax and diaphragmatic hernia The absence of blood from the vomitus, the absence of peritonitic tenderness, a study of the temperature, the leukocytes, etc , will help in excluding subdiaphragmatic accidents

---

[11] Krehl Der Verschluss der [illegible], Nothnagel's System, xv, 300.

Obrastzow[17] calls particular attention to this resemblance to surgical accidents which my own experience corroborates Engelhardt's case also illustrates this point

If these cases are recognized, the importance of absolute rest in bed for several days is clear It would also seem to be far wiser to use digitalis, strophanthus or their congeners than to follow the routine practice of giving nitroglycerin or allied drugs The hope for the damaged myocardium lies in the direction of securing a supply of blood through friendly neighboring vessels so as to restore so far as possible its functional integrity Digitalis or strophanthus by increasing the force of the heart's beat, would tend to help in this direction more than the nitrites The prejudice against digitalis in cases in which the myocardium is weak is only partially grounded in fact Clinical experience shows this remedy of great value in angina, and especially in cases of angina with low blood pressure, and these obstructive cases come under this head The timely use of this remedy may occasionally in such cases save life Quick results should also be sought by using it hypodermically or intravenously Other quickly acting heart remedies would also be of service

LAWS RELATIVE TO THE SANITARY CONTROL OF PUBLIC EATING- AND DRINKING-PLACES *

WALTON FOREST DUTTON, M.D
CARNEGIE, PA

The sanitary knowledge of the ancient Egyptians was tolerably extensive, and, gauged by the measure of those early ages, by no means unimportant It corresponds to the reality in both the actual and chronologic points of view to consider the Jews (Moses) as creators of public hygiene

The Egyptian priests bathed their bodies twice every day and twice every night This was not altogether a priestly custom for history relates that Pharaoh's daughter bathed daily in the Nile

The ordinance of Leviticus xv, 11, was made the basis of a sanitary system of ablutions before meals, for which vessels were provided, and further, to secure against defilement in any other way, a system of washing of cups, pots and brazen vessels was devised (Hebrews ix, 9 and Mark vii, 4) In Leviticus xiii and xiv it is noted that the patients' clothing, the vessels they used and the houses they lived in were disinfected Later St Mark vii, 4, reads "And when they come from the market, except they wash, they eat not And many other things there be, which they have received to hold, as the washing of cups and pots, brazen vessels and of tables "

The rich of Greece (460 B C) had their private baths and the Athenians their public baths The Athenian maiden, unlike her Spartan sister, did not think it proper to exhibit her bodily skill and beauty publicly in her chiton, but taking a bath seems to have been one of her every-day habits, as shown by numerous bathing scenes on vases

When in the Greek home, as guests, persons reclined comfortably at the table and water was poured over the hands and dried with individual towels Then small portable tables were brought After the repast was over, the tables were removed, the floor swept clean of crumbs, bones and the like, and once more water was poured over the hands The use of knives and forks was unknown at this period, whence the custom of washing the hands and drying them on towels

Roman laws provided no protection for the individual In older times of Roman history, lavatrinæ or wash-houses were next the kitchen Later, hot, sudatory, tepid, cold and shower baths were in the homes At the end, as at the beginning of a meal, the hands were washed with scented soap The public baths, such as the thermæ of Veleia and Pompeii and the baths of Caracalla, in Rome, (217 B C), were masterpieces of architecture It has been calculated that 62,000 people could have bathed any hour in the public baths of Rome, not to mention the private baths

Hygienic measures were a part of the religious observances among the ancient Jews, as well as among the peoples of Assyria and India The measures were enforced by their priests Among the Greeks this duty was transferred to the physicians Through the whole the Jews enjoyed a remarkable immunity from epidemic diseases, while their Christian neighbors perished around them In medieval and modern history, down to the present time, the filthy habits of the Christian population offered a premium for plagues of every kind Two centuries ago the mortality of London was eighty per thousand Until a comparatively recent date the mortality of our large cities compared favorably with the London of two centuries ago

The gradual deviation from the sanitary ideals of mosaic times, to the beginning of the twentieth century, was such as to lead to the belief that the standard of civilization was declining, instead of rising It is not an uncommon thing to see, in the densely populated sections of our large cities, in the small towns and even in country districts, hygienic and sanitary conditions relative to public eating- and drinking-places, that would put primitive peoples to shame On a tour of inspection I saw many eating-places where no provisions were made for ablutions before meals The knives, forks, spoons and dishes (some the cat and dog had used) were rinsed, not washed, in water that had not been changed for days Among the patrons of these eating places were whites, blacks and mongols The diseases represented were tuberculosis, syphilis, gonorrhea trachoma, scabies, tinea sycosis, and no doubt typhoid, scarlet fever, etc In another series were found eating-places where provisions were made for ablutions of face and hands but all used the same bowl, towels, soap, etc The eating- and drinking-vessels were washed in pans, but no attempt was made at sterilization

In first-class eating-places provision is made for the hygienic and sanitary comfort of the patrons, yet it is the personal element that enters into the protection of the individual in the higher class places

---

[17] Obrastzow and Straschesko Zur Kenntniss der Thrombose der Koronararterien des Herzens Ztschr f klin Med 1910 lxxi 110

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association at the Sixty Third Annual Session held at Atlantic City, June 1912

The standard of public drinking-places may be classed in much the same way as the eating-places, with this exception even in places of the highest class, glasses and bottles are only occasionally sterilized In lieu of the foregoing conditions I would suggest the following

1 The enactment of laws relative to the sanitary condition of public eating- and drinking-places, which shall provide for (a) the personal hygiene of owners and employees and (b) sanitary precaution on the part of owners and employees

2 The owner of each and every public eating- and drinking-place shall be licensed under such law, such license to continue in force as long as there is no violation thereof

3 Any and every glass, cup, dish and other eating- or drinking-vessel or utensil used in any hotel, saloon, restaurant, drug-store, soda-fountain, or other place of public refreshment in the state shall be sterilized in steam or boiling water after being used by any patron and prior to any further use thereof in eating or drinking by any other patron, and no such glass, cup, dish or other eating- or drinking-vessel or utensil after use by one patron in eating or drinking, shall be offered or be permitted to be used by any other patron without having first been thoroughly cleansed and then sterilized in steam or boiling water

4 No person, firm or corporation shall at any time or place keep, expose, offer or prepare for sale, or shall store pending sale, any article or substance of human food or drink in any place or premises which is not, at such time, screened so as to prevent insects from having access to such article or substance, and no person, firm or corporation shall at any time or place keep, expose, offer or prepare for sale, or shall store pending sale, any article or substance of human food or drink in any place or premises unless such article or substance is pure and wholesome and entirely free from contagious and infectious bacteria

5 No drinking-vessel, used in common or to be used in common, shall be kept, exposed, provided or permitted in any railway station, public or private school, public playground, public park, public building or in any place to which the public are admitted

6 No drinking-vessel used in common shall be exposed, kept, provided or permitted in any mill, factory, railway train, ship, boat, hospital, private or public institution, public works or in any place where a number of persons are employed or assembled

7 No table-linen or coverings, towels, cloths, sponges, soap, combs or water used in common or to be used in common shall be exposed, kept, provided or permitted in any public eating- or drinking-place

8 No person or persons shall be served food or drink at any public eating- or drinking-place until they shall have thoroughly cleansed the hands and face with soap and water, as provided for in Suggestion 7

9 No person or persons known to be suffering from an infectious or contagious disease shall be served food or drink at or in any public eating- or drinking-place unless isolated from other patrons under proper sanitary conditions, in order that no other patron shall in any way be exposed or endangered in any manner whatsoever to said infection or contagion

It may be argued that no sanitary system can supplant present conditions unless entailing great expense and inconvenience To this I agree, but whatever is humane and promotes the progress of civilization is expedient and necessary I would therefore suggest the following as a few of the many things that may be used sanitary paper cups, straws, cupless attachments on faucets, sanitary systems of drinking-fountains in mills, factories, stores, institutions, etc, bubbling fountains, which make cups unnecessary, paper napkins, individual towels, cloths, soap, installation of systems for rapid cleansing and sterilization of dishes, glasses, cups or other utensils, used in or about public eating or drinking places

Most, if not all, of the state boards of health have condemned the public drinking-cup The progressive cities have passed ordinances prohibiting the use of the public cup St Louis has taken advanced measures to enforce the cleansing of any and every glass, cup, dish and other eating- or drinking-vessel or utensil used in or at any public eating- or drinking-place, in running water or clean water This ordinance is a great stride in the right direction, but falls far short of the mark

Railway companies announce that passengers do not demonstrate any great desire for individual sanitary cups Other large corporations maintain that there is no particular benefit derived from the use of the individual cup, and further that the added expense is necessarily great The same argument comes from the individual in respect to slot machines, paper napkins, etc

The solution of this great problem of sanitary control of public eating- and drinking-places depends on the elimination of two factors — avarice and ignorance The mercenary motive of the individual, as regards hygienic and sanitary methods, predominates over his moral obligation to himself and his fellow men Hence the sequence of his reasoning leads to antagonism of laws respecting sanitary science, basing a great deal on the aphorism that "the Lord giveth and the Lord taketh away" The community reasons that the enactment of laws relative to the control of sanitary conditions brings on it added hardships in the form of increased tax-rate, higher cost of living, physical discomfort and infringement on its personal liberty

The state, until a comparatively recent date, did not take marked interest in sanitary affairs It does not at the present time consider seriously the individual The most notable advances made by the state have been when great commercial interests were endangered It is said that "Ignorance of the law excuses no one" Such being the case, we have one of two ways of solving a serious problem The laws must be enacted after the mosaic method and then enforced, which is a most plausible way, or the laws must lie dormant until the masses are educated or have reached a higher standard of civilization

Realizing that any community that wishes to be prosperous must be healthy, sanitarians have taken the initiative in formulating laws to that end, and have accomplished more for their respective communities than has been achieved in this or any other country in the last 2,000 years This may seem a broad assertion, but is it not true? The brilliant and noble work of Gorgas White, Blue, Stiles, Sternberg, Wyman Guiteras, Carroll, Lazear and associates who forged the chain enabling the United States government to have and to hold its many possessions, had the sanction and legal support of the government

Then must we work and wait until we are in the face of a great commercial enterprise, or un[illegible] e are in the throes of epidemics of typhoid [illegible] arlet fever, small-pox, cholera, yellow [illegible] before we awaken to the ne[illegible] of sanitary control? Nc duty It demands of us as medical men and sanitarians to let the light of our knowledge shine and point out the way Let us blot out the black pages of the last 2,000 years and take up the work that the ancient Babylonians, Jews and Egyptians so nobly began It is for sanitarians to apply sanitary science to the affairs of civilization, the masses depend on sanitarians for leaders and teachers

We know what the epidemics of the past have cost us We know how much we have accomplished and how far we have advanced, but we are not left without a guide It is true we do not have a Moses to lead us, but we have more in Hurty, Bracken, Evans, Dixon and their kind, great broad-minded men, unselfish, forceful and considerate of the humane advancement of sanitary propaganda These men have taken the initiative in health work Now let us have the hearty cooperation of every member of the American Medical Association—every person, it matters not his walk in life, interested in the progress of civilization, in securing for every state in the United States laws relative to the sanitary control of public eating- and drinking-places It should therefore be our earnest endeavor and duty to make hygiene and sanitary science one of the basic principles of our civilization

401 Fourth Avenue.

THE CONTROL OF CONTAGIOUS DISEASES IN A MUNICIPALITY *

GUY L KIEFER, MD, D.P.H
Health Officer
DETROIT

Accepting the word "contagious" in its broadest sense, we have a subject before us which would make a better title for a book than for a discussion of this kind, and yet I desire at the start to say that I shall use the word "contagious" as synonymous with "infectious" and "communicable," and speak of contagious diseases as those diseases which are capable of transmitting infection from one person to another in one way or another

If I had been asked ten years ago to give my opinion as to how to control contagious diseases in a municipality, I would have said "by immunization, isolation and disinfection", but after more than ten years in this field of work, it would seem that the answer would be even more simple, namely, "by education." It is true to-day, as it was then, that some acute contagious diseases, principally small-pox and diphtheria, are controllable by immunization, the former by vaccination, the latter by the use of diphtheria antitoxin, but in order to get good results from these methods, it is necessary to have the people of a community so educated that they will submit to them readily and whenever the health officer finds it necessary for them to do so Immunization is undoubtedly valuable in the control of some of the other diseases, among which may be mentioned typhoid fever, but it would be difficult to make any great use of this method in any municipality at the present time because of the lack of knowledge of this procedure on the part of the community Isolation, the second method which has been in vogue for a number of years for the control of contagious diseases is desirable and satisfactory when it can be employed, but it is necessary first to have knowledge of a case before it can be isolated It was because of the fact that so many cases of acute contagious diseases, particularly diphtheria, scarlet fever, measles, German measles and others of that nature were never reported and consequently escaped the attention of the public health officials and could not be isolated, that a system now known as medical inspection of school children was first introduced

Medical inspection of schools, as it is better known, comprises at the present time not only the detection of contagious diseases among school children but also the detection and correction of physical defects and the study of mental defects, but it was originally planned for the purpose of detecting cases which otherwise escaped the attention of the authorities

In considering the isolation of cases of contagious diseases, the question of hospitalization comes to our mind and with it the fact that many cases of contagious diseases cannot be properly isolated in private houses I would not take the position that all cases of all contagious diseases, including typhoid and tuberculosis, should be hospitalized, but on the other hand, I think it is absolutely necessary for the success of the preventive measure known as isolation that in each municipality there should be a properly equipped and constructed municipal hospital for contagious diseases under the control of the board of health in which such patients as cannot properly be isolated in their own homes may be cared for By having facilities for early reception of such patients, it will be possible to reduce not only the morbidity but also the mortality from contagious diseases

Disinfection is the one method of the three that I have mentioned that has been bitterly attacked by some progressive sanitarians, among whom may be mentioned Dr Charles V Chapin, of Providence, R I In a paper[1] read before the American Public Health Association in 1910, Dr Chapin took the position that "terminal disinfection," or disinfection of a room or house after a case of contagious disease has been terminated, really has no value, and he showed by a series of figures that in Providence, where "terminal disinfection" had been discontinued, the results obtained with regard to additional cases arising in the houses in which there had been an original case, were almost as good without "terminal disinfection" as when it had been performed In spite of this opinion, and the opinion of other progressive men, the fact remains that "terminal disinfection,' properly done, does disinfect, in other words, that formaldehyd used in sufficient quantities for sufficient lengths of time, in a room which has been properly prepared, does destroy such infection as may be within the room Of course the method of disinfecting for the purpose of controlling the spread of contagious diseases should not be limited to terminal house disinfection by formaldehyd or sulphur, but should consist in a disinfection during the course of the disease of everything that has been known to have become infected All materials which have no intrinsic value and which have become infected by contact with the patient during the course of the disease should be destroyed by fire, and whenever this procedure cannot be followed, we should resort to boiling, immersing in chemical solutions, or some other method equally satisfactory

If it were possible to apply one or more of these methods, namely, immunization, isolation and disinfection to all of the communicable diseases within a municipality, there can be no question but that the result

---

[1] Chapin C V The Value of Terminal Disinfection Jour Am Pub Health Assn., January 1911.

would be favorable, and the number of cases of such diseases held under control, but considering the appalling ignorance on the part of the public of these diseases and the manner in which they are spread, we have before us, as I have said earlier in my discussion, a problem of education

EDUCATION AS TO CONTACT INFECTION

It seems to me that the public health official who hopes to accomplish much in the future in the control of contagious diseases must be the one who will best educate the public in his community in the necessity for such control In speaking of the need of education among the general public, we must not forget that the *medical profession needs some instruction.* While it is true that the majority of the profession are in the front rank of our work for the prevention of disease in all of its phases, it is equally true that a good-sized minority are absolutely indifferent and many of them ignorant in this respect

In the campaign of education which it is necessary to conduct vigorously for the control of contagious diseases, we must first correct some erroneous ideas which have existed in the minds of the public and of some physicians for years The theory of aerial convection of contagious diseases must be eliminated from their minds, and the fact that all of these diseases are transmitted by direct or indirect contact substituted in its place So long as the people and many of the medical profession believe that these diseases are spread broadcast through the air, just so long will it be difficult, if not impossible, for us to make much headway in our fight against their spread Not many years ago nearly all text-books on contagious diseases took the position that while all of these diseases are certainly transmitted by contact directly or indirectly, they may also be carried through the air for a shorter or longer distance The most modern text-books deny that any of the acute contagious diseases are carried through the air except small-pox, and for some unaccountable reason nearly every author makes an exception when it comes to a consideration of this particular disease As far as my experience goes, I am just as convinced that small-pox is not carried through the air as I am that scarlet fever, diphtheria, measles and other acute contagious diseases are not transmitted in that way During the winter of 1902-1903 there were 1,023 cases of small-pox in Detroit, and the outbreak began in the Polish district of the city The cases did not spread from one house to the next as might be expected had they been transmitted through the air, but they went from one family to the family of a friend or relative who lived, in some cases, a short distance, in others a considerable distance away, but had been in contact with the infected household In this epidemic it was possible to trace the origin of nearly all the cases, and never did we fail to find direct or indirect contact as the cause of the transmission of the disease According to the old theory, the "striking distance" of small-pox is several thousand feet During the past ten years we have treated nearly 1,500 cases of this disease at the municipal small-pox hospital, at one time we had 104 patients confined there, and during all of these years we have had but three cases within the reputed "striking distance" of the hospital These cases were contracted from other cases outside of the hospital with which the patients had, to my personal knowledge, been in contact

The building which had been occupied in 1902-1903 by this large number of patients with small-pox has since been remodeled and is being used as a tuberculosis sanatorium and hospital, and the small-pox patients are kept in a separate building, but located on the same grounds and not more than 500 feet away Before this complete change was made, the small-pox patients were confined in one part of the large building and the tuberculosis patients in another part with an air-space of only 3 feet separating the two, during that time and since then, no case of small-pox has developed on the grounds outside the small-pox hospital, without reference to the vaccination status of the patients admitted to the tuberculosis sanatorium

It is my opinion that not only the acute contagious diseases including small-pox, are transmitted by direct and indirect contact alone, but that this applies with almost equal force to such diseases as were formerly classed as infectious, of which typhoid fever and tuberculosis are the type It is undoubtedly true that typhoid epidemics are traceable to infected water- and milk-supplies, but we have cities in which the water-supply and also the milk-supply, as a whole at least, are beyond suspicion and in which we have every reason to suppose that they are safe as far as typhoid infection is concerned I believe Detroit is such a city There may be, and occasionally there are, cases traceable to infected milk from an infected dairy, and I have traced such cases, but as a whole as I have said, the milk-supply is not infected or we would have many more cases How then, is the disease transmitted? In the very interesting and thorough investigation made of the cause of the transmission of typhoid in the United States Army during the time of the late war with Spain by a committee appointed by the government, of which Dr V C Vaughan of the University of Michigan was chairman, the conclusions, as I remember them, were that the disease was spread in three ways, and in the order of frequency they were (1) personal contact, (2) flies, (3) water-supply All the latest studies of the subject in Germany lean toward the side of direct personal contact rather than the indirect one of transmission by flies and infected water if, indeed, these modes of transmission may be considered "contact," as I would have you believe Certain it is that no one nowadays adheres to the theory of air-convection as far as typhoid fever is concerned

With tuberculosis the proof of "contact infection" may seem even farther away to some than is the case with typhoid, and yet the more this disease is studied, the more evident its method of transmission becomes Not many years ago it was believed that the disease was hereditary, but bacteriology turned on the light and dispelled this erroneous theory Now we know that consumption is spread from infected persons, principally by the "droplet method," which certainly requires close proximity on the part of the victim, or by means of particles of dried, infected sputum gaining access to the mucous membranes of the mouth and throat of the susceptible individual But is it not reasonable to believe that in the great majority of cases this infected material may be brought to the lips and mouth of the victim by his own fingers which have become infected in one of the many ways in which this is possible? Or if a man, perchance carry some infected material on the bottom of his trousers or even on his shoes and then come into close proximity with these infected articles, is not that contact infection? If consumption were so universally carried through the air as has been supposed, would there not be more cases even than there are now? Certainly not so many of us are immune to the di-

REPORTING VENEREAL DISEASES

The first step necessary in our campaign of education, then, is to teach the public something about contact infection, and in this instruction we must not forget to lay emphasis on the fact that contact resulting in the spread of the disease may be had not only with the patient himself, but *with an infected person or thing*, and under this head let us not forget the danger of the ever-present house-fly. The fly that has been in contact with the patient certainly becomes an infected "thing," and one which may be the cause of our taking the disease from which the patient is suffering. As we progress in our campaign of education, it is necessary for us constantly to add to our list diseases to which formerly little attention was paid. In scientific discussions of the past, a fine distinction can always be found between contagious and infectious diseases, and yet there is one class of diseases which is certainly contagious, which is dangerous to the public health, and which is perhaps more prevalent than any one of those which have received more attention at our hands and which, until recently, has been mentioned, if at all, only in a whisper. I refer now to the venereal diseases. The time has come when the public must be taught to lay aside false modesty and prudery and must learn something of the terrible results and of the immense mortality following attacks of gonorrhea and syphilis. Here again is an example in which the method of isolation, so highly recommended, has failed utterly in the past because of the fact that the cases are not known to the public health official whose duty it is to isolate them. Each municipality should have a properly equipped hospital for the reception of the most infectious cases of this kind.

In order that cases of venereal diseases may come under control of public health officials, they should be reported just the same as other contagious diseases, but a mere suggestion even to the medical profession that venereal diseases be reported to public health officials encounters disapproval. At a recent meeting of the Michigan Health Officers Association I had occasion to talk on this subject and made the suggestion that the association endeavor to secure legislation during the next year requiring the reporting to public health officials of cases of venereal diseases. The suggestion met vigorous opposition on the ground that physicians would not report such cases and could not be asked to do so. Ten years ago the same opposition was met when it was suggested that tuberculosis be reported. It was argued that the disease was not contagious in the same sense as is, for example, small-pox, that the board of health would isolate all cases and placard the houses, that a patient should not be told when he is suffering from tuberculosis and that the public should not be told about *the affliction of the patient*. All of these objections have been met and overcome and tuberculosis is now being reported at least, in most cases. In the case of venereal diseases the objections could be even more easily met. The diseases are certainly contagious, as much so as any acute contagious disease that can be mentioned. It will not be necessary to isolate all cases and placard the houses, it is certainly wise and proper to tell a patient when he is suffering from either of these diseases, and as far as the publicity of the report is concerned, that can be overcome in the same way as has been done in laws requiring the reporting of cases of tuberculosis by providing for a protection of the records and making it a violation of the law for the health officer to divulge any of the information contained in the report except for the purpose of enforcing the tuberculosis law itself.

CONTROL OF TUBERCULOSIS

The good results attending the campaign of education for the control of contagion in a municipality are perhaps best seen in the case of tuberculosis. A few years ago this problem looked so large that it seemed impossible to know how to take hold of it, but now the work has become systematized in most cities to such an extent that it is moving along as easily as the work for the prevention of any of the other diseases. In Detroit we had no knowledge of the whereabouts of our cases of tuberculosis until about six years ago. At that time an effort was made to do something in the way of control of this disease, and the first thing necessary was to locate some of the cases. Accordingly, a nurse undertook a house-to-house canvass for the purpose of educating members of the household in the prevalence and danger of tuberculosis and in the methods of its prevention, and *incidentally for the purpose of locating some cases of this disease*, at the same time a clinic was established in charge of a physician and nurse in the board of health building for the purpose of examining such applicants as might apply, and to give them medical advice and, if necessary, a proper diet. It was not long before a number of cases were located, and subsequently the Municipal Sanatorium was started for the reception of the most infectious cases. Now we have nearly 400 patients under the care of the board of health physicians and nurses outside of the sanatorium, and seventy-five constantly receiving sanatorium care. In the meantime and partly as a result of the work done in Detroit, a law was passed by the state legislature providing for the reporting of all cases of tuberculosis in Michigan, and while this law is not being universally obeyed, it has had the effect of adding a great many cases of tuberculosis to the statistics of the departments of health of the state and of the various municipalities, and has given the health officials an opportunity of having general supervision over all these cases.

REDUCTION OF INFANT MORTALITY

Again, the good effect of an educational campaign conducted by the department of public health can perhaps best be seen in the work that is being done all over the country for the reduction of the excessive infant mortality. In Detroit there was a reduction in the number of deaths under 1 year of age during the four summer months, June to September, 1911, as compared with 1910. This reduction was due to a great extent at least to the instructions given by the board of health nurses to mothers on infant hygiene, to the advice and medical attention given babies and mothers in the mothers' clinic at the board of health building, and to the careful supervision of the milk-supply by the milk inspection department. The instruction referred to was given by six nurses who visited the homes when babies were born and told the mothers how to keep the babies well. During the winter months the same nurses act as school nurses in our city, during those months, when it might be expected that it would be easier to reduce the infant mortality, the reduction in 1911 over 1910 was only very slight. During the four summer months there were 139 less deaths in 1911 than in 1910 and during the remaining eight months the total reduction was only ninety. This seems to indicate that what is necessary for the promotion of this sort of public health work is instruction, and as far as possible, instruction by word of mouth from the public teacher to the community

What has been said about the work for the prevention of tuberculosis and for the reduction of infant mortality applies equally well to the restriction of all contagious diseases It is necessary for a progressive department of public health to have a large corps of competent trained visiting nurses, the larger the number and the more trained, the better Each case should be promptly reported to the board of health and, after being properly recorded, it should be investigated by a nurse In her investigation the nurse, besides giving instruction to the family in the prevention of the particular disease, could make a note of the housing condition of the family and in this way this most important branch of public health work would receive proper attention and this predisposing cause of contagious disease — insanitary housing — would be much improved

In closing I desire to say, as I said in the beginning, that the control of contagious diseases in a municipality must be accomplished by education, and this education can best be given to the public by trained nurses in the employ of the board of health

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS DUTTON AND KIEFER

Dr. Pauline M. Townsend Hanson, Marshalltown, Iowa To my mind, the idea of reporting, quarantining and confessing about other diseases and not reporting the social diseases has been a farce for all these years Who that understands would not rather have small pox than have one of the venereal diseases? Dr Dutton suggests laws requiring the cleanliness of patrons at a restaurant before eating their meals, and that all public eating houses shall have provision made so that the diner may wash up before eating This we all know would add to the cost of maintaining eating establishments and add to the final cost of the meal Thousands of the well fed do not realize the effect of 10 cent meals If any physician of the American Medical Association had to live on 10-cent meals three times a day for a year, that physician would be very apt to feel sick and grievous, but there are thousands of men women and children who cannot afford ten cents three times a day for a meal. It is a great deal more insanitary to be without a meal entirely than it is to eat a dirty meal. These people who cannot afford the ten or fifteen cents to pay for their meals go to the garbage barrels to find their food and dirt on the hands is as nothing to the dirt that is found in the food thus gathered All the dirt on hands which is conveyed to the mouth by the handling of food in eating is as nothing to the dirt that is found in the food during its manufacture from the original products, laws that merely require cleanliness of the things that are going on the table will not touch the problem until there is supervision of food from start of manufacture to eating time In connection with this problem, comes the problem of poverty In this day of speedy processes of manufacture of increased scientific knowledge and of rapid production, it is a disgrace that we have poverty existing in America *or anywhere else in the world. It is not at all necessary*, it is one of the things we have to get rid of, and it is one of the problems for this section to take up I do not see why we could not have a committee from this section to investigate into the matter of the speediest method of doing away with poverty in America just for sanitary reasons

Dr Otto P Geier, Cincinnati Cincinnati is building a municipal hospital which will cost over two million dollars It was with a great deal of difficulty that a few of us were able to impress on the hospital commissioners that it was safe to place the small pox hospital near the group of contagious disease buildings Every speaker this afternoon has emphasized the need of education Dr Kiefer speaks about the public teacher Who is properly the public teacher? Dr Kiefer says the public teacher should be the nurse In this crusade of preventive medicine we are gradually narrowing the field of the physician Most of them are cooperating with the health officer in bringing about this lessening of their field and it is to their credit There is a minority who cannot cooperate because with them it is a matter of bread and butter Possibly in discussing these questions we have overlooked the economic side Should we not make the physician a part of the program of public educational work? It is said that the average income of the physician in the country to day is a thousand dollars a year I would like to suggest this question to Dr Kiefer Do we properly value the physician in this program of education? Are we replacing the work which we are taking away from him by preventive medicine? In this campaign of education we must, in self-defense, take care of the physician if we care to have this work progress to its ideal limit If we do so, it will first bring into line that small minority who are fighting for their bread and butter and lastly I think it will bring a better recognition from the public itself, because, after all, free service is never appreciated

Mr. W A. Howe, Albany N Y It seems to me we ought to be willing to do more for the general practitioners They are the men who are suffering most and who will continue to suffer most from this progressive wave of preventive medicine If we are going to conduct a campaign of education along these lines let us utilize for that purpose the family physician that he may profit rather than suffer therefrom Let him be the teacher as he is so well fitted to be, the cooperator, the contributor to our success Within the last three weeks we have placed in the hands of every member of the graduating class of every medical college of the state, a package of literature bearing on public health This contains the Public Health Law various leaflets published by the Department on Communicable diseases and much other material instructive and useful to them as prospective practitioners We are endeavoring to acquaint them with the various resources of the department and to urge their more liberal employment by the medical profession We are endeavoring to cultivate a closer cooperative plan between the medical profession and our department, believing that no department of health can be stronger than that which is measured by the willingness of the medical profession in its cooperation We believe that just in proportion as we can interest the practitioner in our work so are we going to succeed, and that just in proportion as we embarrass the practitioner or discourage him so will success with us be impossible So thoroughly convinced are we in New York of the necessity of this line of activity that steps have already been taken to introduce into the various medical colleges a uniform course of instruction in public health This plan has already been approved by the deans of several of our leading medical colleges, and it is my expectation that it will receive their unanimous consent within the next fortnight Our scheme includes lectures by representatives of the State Department of Health, field instruction to the medical students by the municipal health authorities, and instruction by members of the faculty of the several medical colleges We also hope to perfect the plan in such a manner that one lecture will be given in each of the ten medical colleges by a representative from each of the other colleges on some subject pertaining to public health This educational movement among the medical colleges we regard as highly important believing that by successfully conducting it, within a few years we will secure a large number of medical men trained in at least the rudiments of sanitation, far better capable of making efficient health officers and more susceptible of interest in public health questions This is one of the lines of practical public health instruction which I believe we as health workers must encourage and promote

Dr Seneca Egbert, Philadelphia The question of popular education in public health work is an old one As a matter of fact it seems to me that we must realize that the greatest field of work is among the laity Under force and stress of public opinion we have moved our municipal hospital in Philadelphia miles away from the center of the city It would be much better for Philadelphia if we could have a number of sec tional hospitals, each serving its own neighborhood We might easily enough have these hospitals for infectious diseases if we could get rid of that bugbear in the minds of the people that if there is small pox or scarlet fever on the other side of the street it is going to be dangerous for people who live on this side We know that that is largely nonsense I believe with Dr Kiefer that the theory of the air transmission of small pox is largely a fallacy to day We owe a great deal to Dr Chapin of Providence for what he has taught us, although we may not agree with him entirely

When we can impress on the people the importance of vermin, the fly, the bedbug, etc, and when we can get the public to realize that contagious diseases are transmitted by such agencies or by contact and not by germs floating through the air, then I think we can get people to appreciate what they must do in order to eradicate these diseases, and we can then get to the point where we can have the hospital in the vicinity of the home One can scarcely blame a mother to-day for objecting to send her child with measles or scarlet fever to a hospital which is possibly a day's travel distant I am not much in favor of compelling people to do things by law which they do not understand and which they do not want to do I think we are teaching the people in Philadelphia how to take care of their babies For instance, Dr Neff's reports for certain wards show a considerable saving of infant life It is because the people have been taught, and because many of our health inspectors have been brought into contact with the people and have been able to show them that their neighbors' children were doing the damage in spreading the disease and that they themselves could help in checking it I know that this matter of popular education will appeal to people if we can put it in the right way A great many of our social workers are doing splendid work, but we must not forget that not every person can go out and teach health matters without preliminary training, it takes considerable training before people are able not only to teach but to get those whom they are teaching to absorb and apply what is taught

Dr Mary Dunning Rose, New York Nurses will work for $1,000 a year or less and give their entire time If physicians were asked to do for $1,000 a year the district work which these nurses are doing, and devote their time to it, I think that but few would respond to the call Again, if the number of physicians who register in the United States continues to diminish—there were more than a thousand less in 1911 than in 1910—it seems as though it will not be many years before physicians will be able to obtain more than $1,000 a year, even though preventive medicine is pushed forward as rapidly as possible

Dr. Walton Forest Dutton, Carnegie, Pa I do not think the scope covered by my paper was at all too broad The suggestions relative to the sanitary control of public eating and drinking places are appropriate to present day conditions If we will stop and consider just for a moment, we fully realize the necessity for such laws as I have advocated Since this paper was written, four cases of gonorrheal ophthalmia have come under my service The infection was directly traceable to a towel used in common by the men and boys employed in a certain part of a mill Another patient employed in a down town office gave about the same history

Some days ago while drinking at a soda fountain, I saw the same glass and spoon which had been used by a person who had a chancre at the angle of the mouth, rinsed off hurriedly, not washed, and placed on the working board Ten minutes later I saw the same glass, and spoon, filled and handed over to a little girl about 10 years of age In the name of Him who said 'Suffer the little children to come unto me," is there no help? Must we work and wait on the education of the masses and in the meantime sacrifice the lives of thousands of men, women and children to years of loathsome disease, suffering and death?

For the sake of the innocent mother, sister or child in your own home or that of your brother who must of necessity patronize public eating and drinking places, assist in enacting laws which will be an honor to yourself, to your neighbor and to your country

Dr Guy L. Kiefer, Detroit I agree with Dr Howe in his statement that the principal thing necessary for the success of public health and work is the cooperation of physicians, and, of course, the cooperation of the people There is no question about that I desire to emphasize what I have said about employing nurses as teachers In the first place, as Dr Rose said, you cannot get many physicians to devote all of their time to the work for $000 a year, in the second place, the more of this educational work there is done, the more successful your public health work and the more business you make for the physicians There are always going to be people in every community who are going to employ the physician to do the very thing that the nurse is doing through the public health department I agree absolutely that sanitary education is better than sanitary legislation You cannot enforce legislation unless you have the education and the public sentiment back of your laws, but the way to give the people this education is by sending a nurse to the house, because, while the physician might in many cases be more able to give knowledge, people will not listen to him as they will to the nurse. The nurse goes to the home and talks to the mother, who will not listen to the physician If physicians go around giving this education, the physicians at large will think that the former are getting into their families, and there is the question of professional jealousy

---

PROCEDURE IN QUARANTINE PRACTICE

DESIRABILITY OF THE RECONSIDERATION OF PRESENT METHODS, ESPECIALLY IN RELATION TO THE "MINOR" INFECTIOUS DISEASES *

J W KERR MD
Assistant Surgeon-General United States Public Health Service
WASHINGTON, D C

Quarantine has been defined as "the adoption of restrictive measures to prevent the introduction of disease from one country or locality to another" In the broader sense, therefore, it includes many measures, following the notification of disease, to prevent the transmission of the infection from the sick to the well Among these measures may be mentioned placarding of buildings, observation and surveillance of patients and contacts, prohibition of public funerals, disinfection, etc

In recent times, inquiries have been frequently made to determine the degree of uniformity that prevails regarding restrictive measures and their manner of enforcement by health authorities to prevent the spread of diseases such as diphtheria and scarlet fever These inquiries disclosed the facts that while placarding, isolation, disinfection and prohibition of public burials were in general insisted on, great differences existed in the provisions governing the character and duration of isolation, because of diversity of opinion with respect to the modes of infection and the period of infectivity

The object of this paper is not to deal with such measures as placarding, disinfection, etc, in regard to which more or less uniformity exists, but to invite attention to those provisions relating to observation and surveillance of infected and exposed persons

REASONABLE AND UNIFORM PROCEDURES

One of the principles governing the conduct of quarantine is that it should be reasonable and based on scientific knowledge respecting the period of infectivity and modes of transmission of communicable diseases. Quarantine of places, persons and things should extend

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association at the Sixty Third Annual Session held at Atlantic City, June, 1912

over the least possible period of time consistent with safety, should cause the least possible expense and inconvenience, and should be reasonably effective in preventing the transmission of infection to other localities

The great importance of reasonable and uniform procedures has led practically all civilized countries to enter into international agreements, in which are specifically outlined the quarantine restrictions to be observed by the respective governments for the control of certain diseases These diseases are plague, cholera and yellow fever This international cooperation suggests like action on the part of state and local governments looking to the adoption of definite and uniform methods of procedure in local quarantine practice That there is need for greater uniformity is evident

In practically all of the states and territories the duration and conditions of quarantine in different diseases are specified by the regulations of the respective state and territorial boards of health In certain jurisdictions, on the other hand, such as the District of Columbia, Ohio, Delaware, Idaho and Utah, the duration of quarantine of certain specified diseases is fixed by law In Iowa quarantine may be imposed only in cases of scarlet fever, small-pox, diphtheria, cholera, leprosy, cerebrospinal meningitis, plague and anterior poliomyelitis

In all of the states and territories, patients may be quarantined at their residences In practically all depending on the disease, they may be removed to a special hospital or other place, and in many there is specific authority to establish contagious-disease hospitals Under certain conditions removal of patients to a hospital is made compulsory in certain states, but in Indiana and New Jersey no person may be so removed except on the certificate of two physicians

In some jurisdictions the duration of quarantine is left to the judgment of the local health authority or physician in charge, and in the several states there are great differences as to the length of isolation in the disease subject to quarantine

EXISTING REGULATIONS

From a collection of the health laws of the several states and territories which I have made and analyzed to some extent a striking variation is revealed in the length of quarantine of the minor diseases A summary of some of these data will be presented to point out such variations and to emphasize the desirability of greater uniformity in view of existing knowledge regarding the causes and methods of transmission of communicable diseases

Small-pox is usually classed as one of the "major" infectious diseases, but it may be cited as an excellent example of the points that this paper is intended to emphasize Although the period of incubation has been more definitely determined in this than in most other diseases, the duration of quarantine of exposed persons varies in the several states from ten to twenty-one days, the stated period depending on vaccination and other conditions Vaccination is recognized by sanitarians generally as a reliable preventive of small-pox, yet in many jurisdictions quarantine of exposed persons is required even after successful vaccination for periods varying from ten to twenty days

Small-pox patients are also subjected to varying periods of isolation after recovery and disinfection For instance, in North Dakota it is five days, and in the District of Columbia, sixteen days In other states numerous periods are fixed from twenty-one to forty days from date of onset and in still others the time of release is fixed by the health officer or physician

Even greater differences exist in the periods during which persons shall be excluded from school on account of small-pox In all the states, either the laws or the regulations require the exclusion from school of persons from infected premises during the period of quarantine and in some states the period of exclusion is prolonged for subsequent periods varying from seven to fifty days

DIPHTHERIA

In the case of diphtheria, which has been declared contagious, infectious or dangerous to the public health in practically all the states and territories, some form of quarantine or isolation is usually required In a number of states these different forms have been classified as "absolute,"[1] "modified" or "special," the modified form being generally practical even in those states where absolute quarantine is prescribed

Duration of Isolation of Diphtheria Patients—In a large number of states and municipalities the period of quarantine of patients is determined preferably by the culture method, but there is variation in the number and time of making the cultures For instance, in the laws and regulations of eight states examined, two negative cultures are required to be obtained twenty-four hours apart In five other states only one negative culture is required, in four others two cultures taken two or three days apart, and in three others the number is not specified Out of twenty cities whose ordinances were examined, ten likewise require two cultures taken twenty-four hours apart, six require one culture, and two do not specify the number or time of taking

In some of the states and cities the length of quarantine is specified in case cultures are not made These periods, following the disappearance of all signs of the disease, are in one state, five days, in one, fourteen days, in eight, twenty-one days, and in two, twenty-eight days In other states, in the absence of cultures, the number of days of isolation prescribed dates from the beginning of the illness or report of the case, and is variously stated to be twenty-one, twenty-eight, thirty and forty-two days In those states and municipalities in which the taking of cultures is not prescribed, the duration of isolation of patients is variously stated to be from ten to thirty-five days from date of onset of the illness or report of the case

Isolation of Exposed Persons—In some states as in Ohio, the duration of isolation of exposed persons is prescribed by law to be the same as for patients In others the time is fixed by regulation with reference to the last exposure, and is variously stated to be from four to fourteen days For instance, in North Dakota it is at least four days or until negative cultures are obtained, in Idaho, five days, in Washington, ten days in the case of children, and in Michigan, fourteen days

Exposed persons usually comprise the members of the family or persons in the house, and in a number of states, as Idaho, Montana, Michigan, North Carolina, South Dakota, Utah and Wisconsin, the length of quarantine applies to all, regardless of age In other states, children in the same house are isolated for longer periods than are adults In Virginia, isolation ordinarily applies only to persons under 15 years of age

---

[1] Absolute ' quarantine implies absolute prohibition of entrance to or exit from quarantined premises Modified quarantine allows under certain restrictions the passing in and out of persons in the family Special quarantine merely prohibits the patients from attending public assemblies and sleeping with others and requires the use of separate eating utensils towels etc

In a large number of states, quarantine terminates after death or recovery of the patient and disinfection of the premises, but in some states the time is prolonged in the case of children In Georgia this additional period of isolation is stated to be seven days after disinfection of the premises In Indiana and Oregon, children, like adults, may be released following disinfection if they receive an immunizing dose of diphtheria antitoxin of at least 1,000 units In Iowa, quarantine must be prolonged for ten days when children are present in the house, unless negative cultures are obtained and the children recently immunized with antitoxin

Diphtheria serves as a good example of the enforcement of modified quarantine In many jurisdictions, as Iowa, Minnesota, Nebraska, Pennsylvania and Wyoming, modified quarantine is prescribed in the interest of wage-earners or heads of families working under certain conditions and observing certain precautions

In Iowa, bread-winners may at the discretion of local health authorities follow their occupations, provided they change clothing on leaving and entering the house, and do not enter the sick-room

In Nebraska, bread-winners and heads of families, if not teachers or persons associated with children, or employed in the milk industry, may be allowed to follow their vocations, provided they change their clothing on leaving and entering the house, and do not attend public meetings

In Pennsylvania, wage-earners are allowed to continue work, provided they do not come in contact with the patient or persons caring for him, and provided they are employed in industries other than the production, manufacture or sale of fabrics, wearing apparel, upholstered furniture, foodstuffs, milk, cigars, candies, etc If so employed, it is specified that they should submit to disinfection and remain away from the premises during quarantine.

In Virginia, all adults over 15 years of age may follow their vocations if not engaged in the production or sale of milk or food, or employed in factories, schools, offices, stores or other places where persons under 15 years are employed, and provided that they do not enter any school, place of public amusement or other place where children are in attendance

Exclusion From School on Account of Diphtheria—Exclusion from school on account of diphtheria usually applies to both patient and children and sometimes to adults in the same house The lack of uniform requirements is striking The length of time varies according to different state and municipal laws and regulations According to some the time ends with the removal of quarantine, and according to others, seven, ten, fourteen and even thirty days later In at least eleven states the period of exclusion extends until the health authorities issue certificates or give permission to return to school In Porto Rico, such certificate or permission may be issued by the attending physician

The culture method is apparently prescribed in only a few state regulations as the means to determine the length of exclusion from school In Massachusetts, convalescents are by regulation permitted to return seven days after the second negative culture has been obtained from the nose and throat and when the physician certifies that all danger has passed, in the case of other children in the house only one negative culture is required

In cities the culture method appears to be more generally depended on, some allowing school attendance as soon as one or two negative cultures are obtained, others requiring an additional absence for seven days or longer In Providence, R I, children in the house are allowed to return after the removal of quarantine, in the better families only one culture is required, and after the expiration of one month all children are usually admitted even if they are bacillus-carriers

SCARLET FEVER

Scarlet fever, like diphtheria, is subject to control by law or regulations in practically all the states and territories, but the control varies much

Duration of Isolation of Patients—In a number of states isolation of patients is required by regulation to be continued until desquamation is complete In some other states regulations require that quarantine of patients shall continue for varying periods after this event has occurred In North Dakota it is five days, in Maryland seven days, and in Georgia, Idaho, Oregon and South Dakota ten days In other states, in addition to completion of desquamation, the absence of other symptoms, including disappearance of inflammation of eyes and respiratory tract, or stopping of discharges, is required In some of these states a minimum time limit is also specified, which is variously stated as twenty-one, thirty, thirty-five and forty-two days

In those states where a time limit only is specified it is variously stated as twenty-one, thirty, thirty-five, forty-two and forty-nine days In Delaware and Ohio the time is ten days following terminal disinfection Regulations in Pennsylvania, in addition to other requirements, specify that the physician must certify in writing that desquamation has ceased and nasal irritation and ear-discharges have healed

In a considerable number of other states the duration of quarantine is not specified except that it shall continue until death or recovery of the patient, freedom from infection, etc

Similar variations exist in the requirements of cities studied, the minimum periods of quarantine being variously stated as fourteen, twenty-one, twenty-eight, thirty, thirty-five and forty-two days In Chicago, in addition to cessation of desquamation and a specified limit of one month, examination by a health inspector is required before removal of quarantine

A committee on communicable diseases of the American Public Health Association in a report[2] on the practice prevailing in eighty-seven cities in which 52,620 cases of scarlet fever were reported in 1910, states that sixty-four of the cities had a minimum period of quarantine which varied from ten days to six weeks This report states further as follows

> In fifty cities the board of health inspects the patient after the report of recovery before release, while the remainder rely on the report of the family physician The cessation of desquamation is the sign of readiness for release in fifty nine cities, although fifty six pay some attention to the condition of the nose and throat Only four will release a patient when nose and throat appear normal, paying no attention to desquamation, and eleven will release when desquamation has ceased even though a nasal discharge exists

Quarantine of Exposed Persons—Quarantine of exposed persons appears usually to apply only to children, but it is stated in the report quoted that in thirty-nine out of eighty-seven cities, all the members of the family are segregated during the continuance of the disease

In some states, by regulations, quarantine of exposed persons continues during isolation of the patient These apply in some states, as Illinois and Virginia, only to children, and in others, as Nebraska and Montana, to all persons in the house In a considerable number of states, modifications similar to those in diphtheria are made in the case of wage-earners In Iowa the regulations prescribe, in case of death of the patient, that the quarantine of exposed persons shall continue ten days thereafter, if there are children in the family

---

[2] Am Jour Pub Health, 1912 ii 121.

Seven, ten and fourteen days after the last exposure are variously prescribed in regulations of other states, but these requirements affect only children, and in North Carolina the requirement does not apply to persons who have had the disease and who submit to disinfection

In a number of other states, quarantine of exposed persons is by law or regulation extended ten days after recovery of the patient and disinfection This in some instances applies only to children and in others to all persons in the house The regulations of Minnesota require extension of quarantine for twenty-one days from the appearance of the last case, wage-earners being exempted as in diphtheria

Exclusion From School —In many states, children and sometimes all persons in the house are required to be excluded from school on account of scarlet fever until release of quarantine and presentation of certificate of discharge In other states, exclusion is continued after release of quarantine or disinfection for variously stated periods, as seven, ten, fourteen, twenty-one and thirty days These requirements in most instances relate to convalescents, but in some, to other children in the house When exposed persons are removed from the house, the period of exclusion is variously fixed at ten and fourteen days

When no definite time is fixed, permission for readmittance to school is required to be furnished by the health officer at his discretion

In the regulations of a number of cities studied, the requirements presumably with respect to convalescents are stated in effect as follows seven, ten, fourteen and twenty-one days from release of quarantine, and thirty-five and forty-two days from the beginning of the disease In other cities the period of exclusion, presumably of children in the house, is twenty-eight and forty-two days from the beginning of the last case

Other variations might be mentioned, but these represent the usual requirements and serve to emphasize the decided lack of uniformity that exists

MEASLES

In the case of measles, the disease is referred to for purposes of control in the laws and regulations of thirty-four states and territories The control is in a number of cases limited to the reporting of cases, and in others to requiring placarding or exclusion from school

Requirements Respecting Isolation of Patients — Requirements with respect to isolation of patients are variously stated in the above-mentioned laws or regulations For instance, in Maryland the duration of isolation is stated as fourteen days after the disappearance of the rash, in New Hampshire and North Dakota at least fourteen days presumably from the date of the beginning of quarantine, in Indiana at least fourteen days or until desquamation has ceased, in Missouri, Pennsylvania and Vermont twenty-one days and in North Carolina twenty-eight days In North Caroline this time may be reduced at the discretion of the health officer In Vermont it is also stated that quarantine shall continue until all complications are over, and in Pennsylvania, until the physician certifies in writing that the patient is well and that nasal irritation and ear discharges have ceased

In the District of Columbia, Tennessee and Utah, isolation is specified to be continued until recovery, in New York, until skin and mucous membranes are clear, and in some other states, as Michigan, it terminates at the discretion of the health authority In Kansas and Virginia, placards only are required

Quarantine of Exposed Persons —Quarantine of exposed persons, when required, generally applies to children in the same house, who are usually not allowed to leave it In North Carolina the period is fixed at fourteen days after the last exposure

Exclusion From School —In the case of convalescents, the stated requirements are various In a number of states, it is provided that they may be readmitted after recovery or release of quarantine In others, the period is prolonged five, fourteen or twenty-one days beyond such release In still other states, the duration of exclusion is left to the discretion of the health authority

In some states, other children in the house are by regulation permitted to attend school if they have had the disease, and there are provisions in several states authorizing children in the same house to attend school ten or fourteen days after removal to another house In Pennsylvania this applies if the house to which they are removed is occupied only by adults

In a number of cities, the period of exclusion from school is variously stated as follows until subsidence of catarrhal symptoms, until recovery or removal from quarantine, seven and fourteen days after recovery, fourteen and twenty-one days from appearance of eruption, and twenty-eight days from beginning of the disease

In some of these cities, other children may be readmitted fourteen days from the appearance of the last case in the house, or in twelve or more days after removal to another house

PRACTICAL APPLICATION OF EPIDEMIOLOGIC AND LABORATORY DATA DESIRABLE

In combating diseases, recourse has been made to isolation to meet not a single condition, but many conditions It is apparent therefore that some variations will of necessity prevail, but they should be as few as possible and based in so far as practicable on accurate data

By careful studies, it would be practicable to bring about greater uniformity than at present exists The results of experiments and laboratory investigations should be utilized, and further investigations made to determine definitely the period of incubation, virulence and viability of infections, modes of transmission, etc, of the diseases in question

Additional facts and opinions have recently been deduced as a result of laboratory studies and epidemiologic work which would justify some modification of quarantine procedure in certain of the communicable diseases For instance, Anderson and Goldberger, working in the Hygienic Laboratory, have shown that the period of infectivity of the blood of measles patients begins at least some hours before the eruption appears, and continues for about thirty-six hours thereafter, and that mixed nasal and buccal secretions are infective about the time of the eruption and forty-eight hours later These observers were unable to infect monkeys with "scales" from measles, and think it highly improbable that desquamated epithelium carries the virus of the disease Lucas and Prizer have likewise shown that the virus of measles is present in the blood-serum at some time exceeding twenty-four hours before the appearance of the Koplik spots and persists more than thirty-six hours after the appearance of the skin eruption On the basis of this work, it would probably be possible for the quarantine of measles patients to be reduced from the usual period of twenty-one days to not more than fourteen days from the beginning of illness, and probably twelve days Similar data with respect to other diseases should be brought together and considered with the view to their practical application in quarantine practice

ABSTRACT OF DISCUSSION

Dr Alexander C Abbott, Philadelphia Dr Kerr has shown us that many of our quarantine methods are not in accord with the newest knowledge In measles, for instance, no account is taken of the latest experimental results In scarlet fever we still lay stress on the desquamated particles as the carriers, whereas our English confrères have for several years been showing us that the disease is more often spread through discharges from the nose and throat than by scales from the skin In diphtheria, we rely on two negative cultures as evidence that the convalescent is free from danger, yet we know that this is not a reliable guide Repeatedly we have observed convalescents at the Philadelphia Hospital for Contagious Diseases whose upper air passages were free from the germs of diphtheria in so far as could be decided by the ordinary culture methods, yet in many cases there has been a reappearance of the germs in the throats of those patients coincident with catching cold Obviously the mucous discharges have washed from the crypts of the membranes living bacilli which had been beyond our reach in efforts to detect their presence The period of quarantine of diphtheria, in localities not possessing advantages of laboratory aid, is usually thirty days It is of incidental interest to note that the average quarantine period for 5,000 cases taken at random from our case book, all of which had been released on bacteriologic indications, was twenty eight days It should be remarked, however, that such averages are also unsafe guides, as among the 5,000 cases tabulated several were in quarantine for from two to three months and a number for only about a week

Dr G T Schwartz, Providence, R I I doubt if we can get at any common agreement until many of the old traditions of ignorant health officers are wiped away Until we discard the old idea that long confinement of a case of contagious disease is necessary simply because the disease has lived in the same house with a certain family, we shall still have trouble The inconvenience is still shown in local boards of health the medical state officer of one town will quarantine a certain case for seven weeks, the neighboring town for three weeks Both receive censure It is a question of common sense, whether we are doing what we actually know we ought to do

Dr B Franklin Royer Harrisburg Pa I want to confirm everything that Dr Abbott has said with reference to the experience, at least while I was in charge, of the Municipal Hospital in Philadelphia concerning duration of quarantine in diphtheria While the average quarantine in that hospital is possibly a little longer than we meet in private practice, it might not be amiss to mention that that average duration of quarantine perhaps included all chronic cases that is, cases with continued irritation of the nasal or buccal mucous membrane or with discharging ears If the average were taken with that group of cases eliminated (many of them remain six and eight weeks or longer), the average time would be reduced to about twenty one days In Pennsylvania we have a minimum limit, which has been fixed by statute, of twenty one days, except in instances in which two negative cultures have been received on successive days when the time may be as short as fourteen days Our request for disinfection from the attending physician is framed so as to make him certify that nasal and oral discharges have ceased. In this way it gives a long quarantine for a group of cases that seem to require it, and releases the average case (except in municipalities that may have some additional requirement) at the end of the twenty one day period

The need for uniformity in quarantine regulations has been felt very keenly in Pennsylvania, and with the adoption of the revised act in 1909, certain minimum regulations were fixed for the entire state There are 875 separate boards of health in the cities, boroughs and first class townships in this commonwealth and the State Department of Health has direct administrative public health control over about 2,160,000 people scattered through 1,350 second class townships, and advisory and supervisory control over the remainder of the state In order to secure uniformity, the very thing that Dr Kerr is arguing for this morning, a minimum standard, was fixed by the act of 1909, that minimum standard is required of all municipalities in the state, each community, entitled to a board of health, however, being allowed to go as much beyond that minimum requirement as they deem wise It is very annoying to the state health officer to find a specific regulation in a certain community, and just across an imaginary line, the boundary of that municipality, an entirely different regulation It is not creditable to public health workers or to the practice of medicine to find these wide variations As worked out in Pennsylvania by the State Department of Health this standardizing of regulations is improving conditions a great deal, and is giving much greater satisfaction to the public

Mr W A Howe, Albany, N Y It is my privilege to be associated with about 1,400 or 1,500 health officers in the state of New York With them there is no one thing which so frequently occasions trouble and embarrassment in the proper administration of the duties of their office as the establishment and maintenance of proper quarantine over children's diseases This universal lack of regularity or uniformity of quarantine methods seems to me to be one of the most serious defects of our present system In my mind we should not only endeavor to adopt a universal state method of quarantining each quarantinable disease, but an interstate system, whereby one state would exert quarantine over the various communicable diseases in precisely the same manner as do the other states I can see no reason why the quarantine of small pox, diphtheria or measles should be different in one state from that in another, and I can appreciate many reasons why a uniform period of quarantine and a standard quarantine card should be put in operation in every state Were the State Department of Health to adopt a uniform quarantine card and furnish the same to the various health officers, who in turn should place such cards on the various communicable diseases reported to them much of the burden of responsibility would be lifted from the local health officer and his results greatly enhanced

Dr. William F Snow, Sacramento, Cal In California, we felt that we must do something, regardless of what the rest of the country was doing, to put our administration cases on some sort of common sense basis Nearly a year ago the State Board of Health appointed a committee of fifteen, which is termed the Committee on Standard Methods of Public Health Administration, and all winter long we have been meeting every little while, we have decided, as a common sense proposition, to report to the State Board of Health for adoption in our form of rules and regulations next fall a number of things which are very far afield from the type of administrative procedure which we have been accustomed to carry out throughout the country One simple measure which we proposed to relieve the local health officer from responsibility has been to make certain simple regulations with reference to two negative cultures in diphtheria, when that does not work, the local health officer shall report that case and all other cases that do not fall within the le *Exposed Persons*—Quarantine of

and do not consider the public point of view We miss a great many cases that are hidden by the public What states report contagious diseases with any degree of accuracy? Very few of them So the reports that you read about the number of cases of measles, of diphtheria, scarlet fever are rarely any indication of the number that actually exists If we can get at the question from the point of view of the public, enlist its interest in our efforts, and then by a process of education point out to it what ought to be done, I think we shall have accomplished a great good The public is willing, if we will only try to help it, but we have in the past put ourselves in the attitude of policemen in dealing with them, and the result is that we have had opposition To illustrate what happens A student made a sanitary survey of Berkeley In the manufacturing district, where everyone knew there were a great many cases of measles, mumps and chicken pox and a few cases of scarlet fever, the map showed a very small number, but when he came to trace the deaths from these diseases many were in that district In the intellectual part of the city he found a large number of cases reported, but a small number of deaths, that showed that where there was unintelligent opposition health office records did not show the facts We should approach this problem from an educational point of view

PLEURAL VOMICÆ

WITH AN ANALYSIS OF SIXTEEN CASES*

ELSWORTH SMITH, A.M., M.D.
Clinical Professor of Medicine Washington University Medical School Physician in Chief St Louis Mullanphy Hospital Physician Barnard Free Skin and Cancer Hospital Consulting Physician Frisco Hospital
ST LOUIS

If left to Nature the destiny of pus within the pleural sac would be first, absorption, second, formation of a pleural vomica, third, perforation of the chest-wall, resulting in empyema necessitatis, and fourth, perforation through the diaphragm into some of the abdominal organs or the peritoneal cavity Of these several results, all quite rare, that by way of formation of pleural vomica is probably the most frequent

Dieulafoy,[1] in the 1911 edition of his work on practice, says

> Considering only its etymology, the word "vomica" (from *vomere*, to vomit) is improperly applied to the symptom which we are about to describe Custom, however, has consecrated it and the word "vomica" serves to describe ejection of pus by respiratory channels just as hemoptysis denotes the ejection of blood from the same passages Custom has even gone further and by an abuse of language has finally included under one term the symptom and the lesion, so we speak of pulmonary, pleural and hepatic vomicæ, that is to say, a purulent collection in the lung, pleura or liver, which has burst into the bronchi and has been coughed up

Dieulafoy's work, moreover, is the only one of the standard text-books consulted which devotes any appreciable space to the subject, and even such special works on diseases of the respiratory tract as those by West[2] and Lindsay[3] give little attention to the condition, the former covering it in two pages, while the latter merely mentions it And so it has seemed that it might be both timely and profitable to direct attention more closely to this class of cases that must appear important because often difficult of recognition, though at times simulating closely other conditions some of which may be incurable, and when thus wrongly appreciated may be the cause of not only great and prolonged suffering to the poor victim of this distressing malady but even of a fatal termination

The present series comprises sixteen cases, ten of which were seen in private practice, of the remaining six cases five occurred in the services of the staff of the St Louis Mullanphy Hospital, and one in the practice of a colleague The reading of the histories of all these cases would trespass on more than the allotted time, and therefore a brief account of Case 14 will alone be presented, as with its symptoms, physical signs and x-ray findings it may well be taken as the type of the group of cases to be studied.

Case 14 —The patient, A L., aged 35, American, married, housewife first seen Nov 14 1911, had never been strong, she had had appendicitis five years ago, and several attacks since. Oct 12, 1911, the patient was operated on in one of her mild attacks of appendicitis One week later pneumonia of the left side developed and a few days later pneumonia of the right side with pleurisy of the left side There was pneumonic sputum About November 2 the sputum suddenly became offensive and copious, filling a sputum-cup in a short while The cough then became most distressing and exhausting November 14, physical examination showed an area of localized flatness below the angle of the left scapula extending to the base below and from 1 inch to the left of the spinal column to the posterior axillary line, over which breath sounds and tactile fremitus were absent Just inside the angle of the right scapula, signs were present pointing to the formation of a cavity in the right lung (Fig 2) A skiagram showed a distinct shadow in the left infrascapular region, the location of the pleural vomicæ In the sputum streptococci were found, but no tubercle bacilli

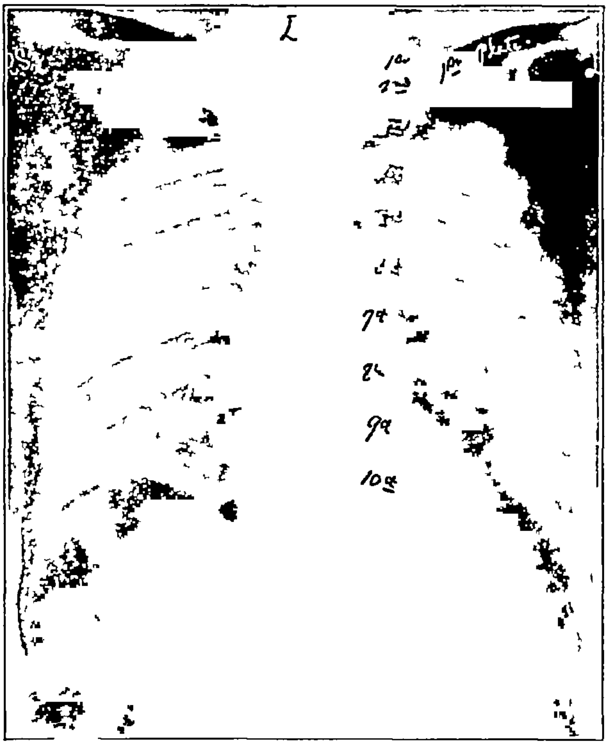

Fig 1 —Case 14 Showing uniform shadow of localized purulent collection in left pleural sac posteriorly below level of sixth rib

Nov 16, 1911, the patient was etherized, the ninth rib resected, and entrance made into a cavity in the left pleura about 6 by 4 inches in dimension, liberating a large quantity of very offensive pus, of the same odor as in bad appendix cases and as of the patient's sputum (Fig 3) The operation was well borne and gave prompt relief from expectoration of offensive pus The patient's condition was satisfactory until December 10, when cough and expectoration appeared to increase and fever returned, in fact, cough and expectoration had never become so completely controlled after operation as in the other cases A second examination of the patient confirmed the finding of a cavity in the lung at about the eighth interspace, just within the perpendicular, going through the angle of the right scapula and about the size of the chest piece of a Bowles stethoscope. Distinct cavernous breathing, pectoriloquy and consonant bubbling râles were heard, limited absolutely to this area, indicating a cavity at this point as the probable cause of the persistence in the symptoms A skiagram showed the shadow of the wall of the cavity with the clear central area

Dec 15, 1911, under general anesthesia resection of the eighth rib was made at a point midway between the spine and the perpendicular through the angle of the scapula, and a cavity was entered (Fig 4) Only a few drops of pus were obtained, but, whether or not as the result of compression of the cavity consequent on partial pneumothorax created by the operation, the patient steadily convalesced and is perfectly well to-day, and physical signs of a cavity are no longer present

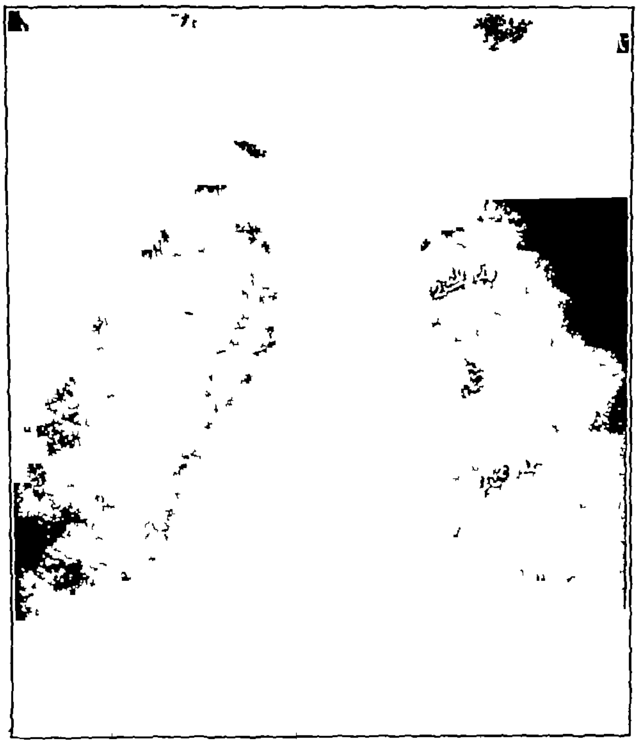

Fig 2—Showing tuberculous pulmonary cavity in right lung with the circular shadow of its walls and its clear central area.

An analysis of the sixteen cases from the following points of view develops some facts of interest and value

Sex—Thirteen males, three females

Age—First decade, one, second decade, three, third decade, three, fourth decade, five, fifth decade, three, sixth decade, one

Occupation—Business men five, farmers, three laborers three, professional men, one, housewives, two, not stated, two

Etiology—Four cases developed during the course of pneumonia one in appendicitis one in an infection from mouth, two in chronic bronchitis with bronchiectasis, three in empyema, three in abscess of liver, four sources, therefore, were below the diaphragm

Bacteriology—In none of the sixteen cases were tubercle bacilli present Case 1 had streptococci and staphylococci and colon bacilli in sputum, Case 12 *Staphylococcus albus* in sputum, Case 14 pneumococci and streptococci in sputum and in pus from the left pleura

Symptoms—Fever of a more or less septic type was present in twelve, absent in two, not stated in two More or less profuse expectoration of pus in every case constituted a most characteristic, distressing and exhausting symptom and caused the statement by the patients in Cases 1, 2, 3, 6, 7 and 9 that this symptom could not have been borne more than a few hours longer if not relieved Onset of sputum was sudden in seven, not sudden in two, not stated in seven In Case 12 a sudden gush of pus was nearly fatal through suffocation and shock In none of the sixteen cases were elastic fibers found in the sputum A marked loss of weight and strength occurred in practically all the cases

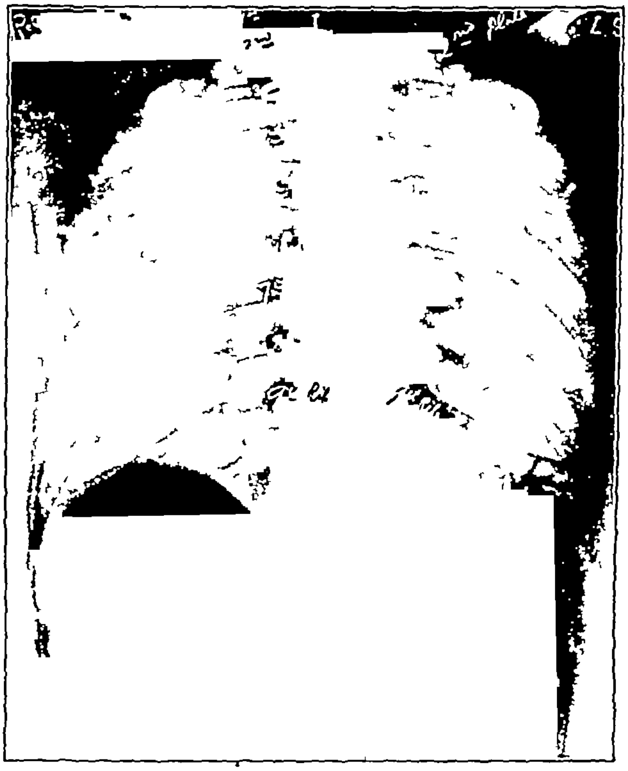

Fig 3—Case 14 Showing resection of left ninth rib with drainage tube in localized empyema cavity

Physical Signs—The important signs of fluid in the pleura, as flatness, and absent or diminished tactile fremitus and breath-sounds, were present over a localized area in the chest in ten of the cases That of pyopneumothorax was present in only two In Case 5, that of a child of 7 years with loud bronchial breathing over the entire involved left side, the muffled heart sounds on the left and accentuated sounds of this organ in its displaced position to the right were helpful diagnostic points, a phenomenon also present to a less degree in Case 6 That signs of pneumothorax were present in only two cases conforms to the dictum that in a great majority of cases of pleural vomicæ pneumothorax does not develop either because of the so-called valvular character of the opening or, as suggested by Osler, that in many of these cases there is no definite opening but a necrosis of pulmonary pleura and a seepage through the spongy tissue of the lung.

Character of Fluid.—This was offensive in six, resembled that of amebic hepatic pus in one, and was simply purulent in the remainder.

Location of Fluid.—Right side in seven, left in four, not stated in five. Of the above pleural collections ten were located in the lower and posterior part of the sac.

Leukocytes.—Slight leukocytosis in two cases, moderate in two, not stated in twelve.

Diagnosis.—The important points in the diagnosis were: (1) the history of an etiologic source for pus, as pleurisy, pneumonia, appendicitis, hepatic abscess, etc.; (2) septic fever, sudden, profuse and constant expectoration of pus, generally offensive and in large quantities; (3) most important of all, the localization of an area in the chest giving the classical physical signs of fluid in the pleura. On these findings had also to be based the differential diagnosis between pleural vomicæ and delayed pneumonic resolution, pulmonary tuberculosis, bronchiectasis, abscess of lung, pulmonary gangrene and the more rare conditions of new growth, lues, hydatid, mediastinal tumor, dermoid cyst, etc. From bronchiectasis, with which, as in Case 3 of this series, it is most apt to be confounded, pleural vomicæ were distinguished by the consideration that in bronchiectasis there is generally history of long-continued chronic bronchitis, gradual onset of characteristic sputum, presence of cavity signs, as cavernous or amphoric breathing and cracked-pot or amphoric percussion note alternated with signs of fluid when the cavity is full, while with pleural vomicæ the signs of pleuritic fluid remain fairly constant because the cavity generally contains only fluid and no air. The same distinction holds true also for abscess of the lung, in which condition elastic fibers may also be present in the sputum. The skiagram, moreover, gives a definite shadow over the site of the pleural vomica, while over the cavity in the lung we have the rather circular shadow of the cavity wall with the clear area in the center, the cavity being not too full.

As bearing on the incidence of empyema and pleural vomicæ, my assistants, Drs. Atwood and Judge, have collected some statistics covering a period of three and a half years at our large General City Hospital at St. Louis and a period of eight years at our St. Louis Mullanphy Hospital. At the City Hospital there were during this period 35,900 admissions, with eighty-seven cases of empyema, or 0.24 per cent. Among the eighty-seven empyema cases there were only three cases of pleural vomicæ, or 3.4 per cent. At Mullanphy Hospital the admissions were 9,782, with twenty-eight cases of empyema, or 0.28 per cent., and among these empyema cases there were three of pleural vomicæ, or 10.7 per cent.

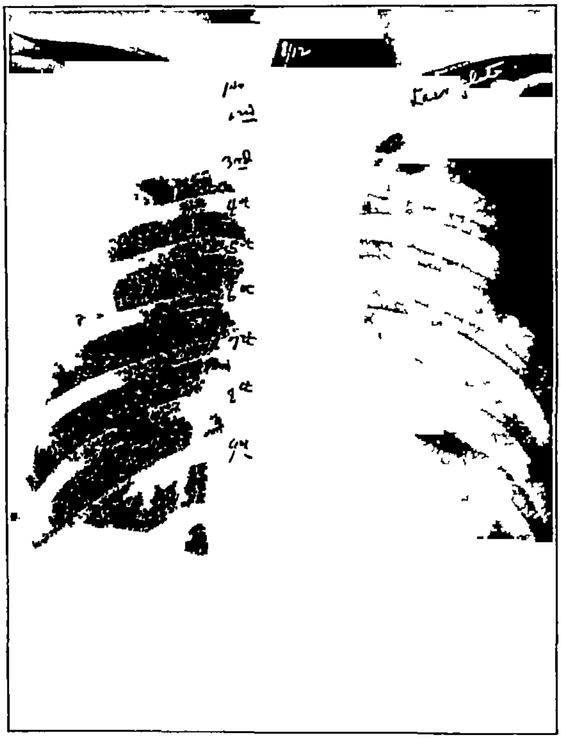

Fig. 4.—Case 14. Showing resection of right eighth rib for drainage of small underlying pulmonary abscess. Note complete clearing up of shadow on left side of chest.

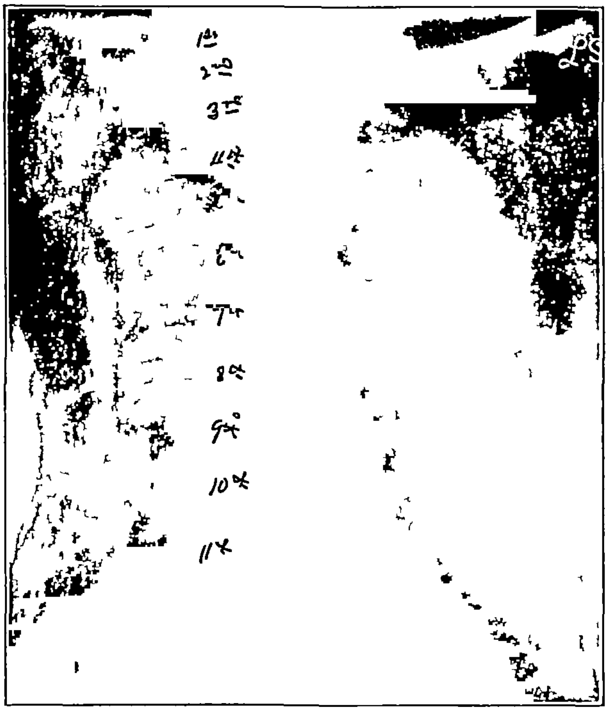

Fig. 5.—Case 13. End result of an extensive thoracic resection for obliteration of a right sided pleural vomica of many years standing. Showing deformity resulting in a case depending too long on Nature for a cure.

Lord[4] found only five cases of pleural vomicæ in 145 cases of empyema, which gives 3.4, the same percentage as at our City Hospital, while James[5] of Edinburgh in his recent work on pleurisy, found nineteen cases of pleural vomicæ in forty-three empyemas, or 44.18 per cent. May not these low percentages of ours, compared to the much higher ones of James, who has given a great deal of study to the subject, mean that perhaps we have overlooked many of these cases and probably classified them with such incurable conditions as inoperable bronchiectasis, abscess of lung, etc.? Lord says that it is a complication frequently overlooked.

In our series of cases:

Four had been considered as delayed pneumonic resolution.
Two had been considered as typhoid fever.

---

[4] Osler: Modern Medicine, iii, 836.
[5] James, Alexander: Pleurisy, p. 139.

Two had been considered as bronchiectasis
One had been considered as pneumonia
One had been considered as pleurisy
One had been considered as abscess of the lung
One had been considered as malignant disease of the lung

In Cases 2 and 4 correct diagnosis had been abandoned because pus had not been found with the aspirator In Case 3 pleural vomica had been overlooked because of the complicating presence of bronchiectasis Case 9 began as a septic pulmonary infarct following cauterization of epithelioma of the floor of the mouth, and for a time was taken to be malignant metastasis to the lung, because of etiology, hemorrhagic sputum, etc In Case 14 pleural vomicæ had also been overlooked because of the complicating presence of pulmonary abscess

If all of these cases could only be appreciated before the onset of pleural vomicæ! This is frequently a difficult task because the empyema is generally quite localized and often interlobar It is at this stage that the skiagram is of great assistance in the localization, and in the very obscure conditions, especially interlobar collections, use of the aspirator under the guidance of the fluoroscope, as suggested by Engelbach[6] and Carman, should be a great help The progress of the majority of the cases in the present series appeared to be toward a fatal termination until relieved by operation The most important complications in unrelieved cases were septicemia, exhaustion, multiple pulmonary abscesses, bronchiectasis, myocardial degeneration, etc

Mortality—While the earlier writers considered pleural vomica a favorable curative occurrence, Saussier,[7] nevertheless, reports fourteen deaths in twenty-eight cases without operation, or a mortality of 48 27 per cent, and Frank Donaldson[8] says it is a serious condition and that if pulmonary fistula persists it will wear out the patient

In our series of sixteen cases the fatalities were three, or 18 71 per cent namely, Cases 4, 6 and 13 In the ten cases in private practice there was one death, or a 10 per cent mortality In Case 4, as post-mortem showed, death was due to pulmonary abscesses and bronchiectatic cavities and also pulmonary gangrene, all of which probably resulted from the persistence of symptoms for twenty-one months before relief by operation In Case 6, while the patient was ill only two months, he undoubtedly suddenly succumbed to myocardial degeneration after apparently having been greatly relieved by the operation In Case 9 death was due to shock following an extensive thoracic resection for obliteration of a long-standing empyema cavity

Treatment—A few points suggested by this series deserve mention The ten patients in private practice were all operated on under ether and all stood the anesthetic well although their condition when placed on the operating-table was bad, and in Cases 1, 2, 6 and 14, especially, the general resistance had been reduced to an alarming degree The only patient operated on under local anesthesia died on the third day from a sudden heart-failure, though the quantity of cocain used was too small to be a factor in the fatal result When the diagnosis of a localized empyema appears quite certain, failure to obtain pus with the aspirator should not deter the surgeon from entering the focus, for in a certain proportion of cases the pus is too thick and viscid to be obtained by the aspirator, as was experienced in Cases 2 and 4, and with precautionary measures against pneumothorax, as by use of Quinby's tracheal insufflator apparatus, invasion of the pleural cavity would be safe

The relief through operation from the distressing, harassing and exhausting cough was in every case nothing short of magical, for in not one, at least of nine of the private cases, was any of the purulent and offensive pus raised through the mouth after drainage had been established through the chest-wall

As to the completeness and permanency of the cures Patient 1, operated on in 1902, and Patient 2, in 1903, are both absolutely well to-day, with entire reinflation of lungs, the former weighing 70 pounds and the latter 40 pounds more than at dates of operation The other recoveries, dating from 1904 to 1911, are also complete, in spite of the fact that the duration of illness before operation was as follows one month in two cases, two months in three, three months in one, seven months in one, one year in three, not stated in six

In conclusion, I simply wish to emphasize that pleural vomicæ cases form a class deserving far more attention than to date accorded it in the literature Many a poor victim of this generally curable malady is doomed to an untimely grave because he is believed to be suffering from such hopeless affections as advanced pulmonary tuberculosis, inoperable bronchiectasis, pulmonary abscess or some of the more rare and fatal types of diseases of the respiratory tract If the localized empyema is diagnosed before perforation, or if every case of copious purulent expectoration be carefully studied and correctly appreciated much untold misery and suffering may be averted and many lives saved

4502 Maryland Avenue

ABSTRACT OF DISCUSSION

Dr Theodore C Janeway, New York These cases should be recognized more frequently and adequately treated by methods employed in cases of empyema Recently I had a case which showed what difficulties may be encountered in making a diagnosis, because of the presence of tubercle bacilli in the sputum This patient, a physician, had had an abdominal operation for supposed appendicitis with abscess formation, an abscess was opened and drainage was instituted, but it was not satisfactory He improved for a few days, then became septic again and a second incision was made for drainage in the flank below without relief After a few days he developed harassing cough and soon coughed up pus in large quantities The condition ran along through the winter, the patient developed clubbed fingers and a slight osteo arthropathy He then came to New York, and signs of a pleural effusion were found with a mass below the diaphragm resembling kidney The sputum was loaded with tubercle bacilli, but nothing was found of a tuberculous nature in the lung by *x* ray or physical examination The history in this case was absolutely distinctive and I believe that the history alone enables a diagnosis to be made A careful study was made The pus that was squeezed from the opening in the flank also revealed the presence of large numbers of tubercle bacilli I believed that a tuberculous kidney, then a tuberculous perinephritic abscess, then rupture upward of this accounted for the apparent pleural abscess The patient went to the Mayo brothers for operation and I have not heard the result Even if tubercle bacilli are present in such cases I should therefore examine with great care before deciding that there is pulmonary tuberculosis present if the history is distinctive of the condition under discussion

Dr. Samuel Robinson, Boston I have reported about seventy five cases of empyema, of these twenty five resulted from some infectious conditions within the lung, and I have come to the conclusion that these so called pleural affections which are localized are generally secondary I believe that the cases decribed are almost invariably the result of some pulmonary infection, in my opinion, these infections occur first in the lungs Occasionally an abscess forms at the periphery of the lung and there is formed a localized accumulation of pus When certain cases of empyema appear they are not primary cases of empyema, but the result of abscesses occurring at the periphery which have burst into the pleural space because it was not walled off

[7] Pepper System of Medicine, iii, 543

[8] Pepper System of Medicine

This class of cases is the most difficult that the surgeon has to deal with, because of the pulmonary involvement. When the surgeon operates, he does so on the empyema cavity and not on the lung cavity which is so deeply situated We know the results that have followed operations on empyemas, secondary and subdiaphragmatic abscesses which have followed cases of appendicitis, duodenal ulcer and other abdominal conditions I think that the first infection in these cases is a pulmonary infection, for the reason that the lung tissue becomes adherent to the diaphragm and because of the expectoration of so much pus It appears that a pulmonary abscess has burst into a bronchus

Dr. Arthur A. Gillette, Rome, N Y I should like to make a report, from the general practitioner's standpoint, of a distinctive case that occurred in a young woman There was difficulty in making an early diagnosis, but the abdominal symptoms were marked They seemed to be referred well up and to the left side of the pelvis especially, and were without any apparent cause The patient gave a history of an acute infection which took place during the grippal season and which pointed to some serious abdominal disease Subsequently there was discharged by mouth large quantities of foul smelling pus which was loaded with streptococci With a hypodermic syringe there was withdrawn from the chest some very offensive pus which was loaded with streptococci I am convinced that this was one of the cases with which we are now dealing The patient recovered without surgical aid, the young woman is now in apparently perfect health and is very active My difficulty lay in determining the point where the infective process was likely to become localized In attempting to locate this point, the general practitioner must be constantly on the watch and must use every facility available and examine every organ In cases in which operation for appendicitis has been advised, I have seen the development three or four days later of a distinct pleural or pulmonary process In my experience I have often found that the symptoms referable to one side result from diseased conditions on the same side especially when associated with abdominal symptoms In the instance I have just reported the local process was on the left side of the chest and back, and the abdominal symptoms were distinctly in the region of the left ovary

Dr. Elsworth Smith, St Louis The case cited by Dr Janeway is one of great interest Dr Robinson holds that all pleural vomicæ are due primarily to a focus in the lung, as he believes that it would be impossible for an empyema to perforate the greatly thickened visceral layer of the pleura While he may be right in many cases, still in a large proportion the pus does actually perforate from the pleural cavity into the lung, and after all it should not be any more impossible for this to occur than for what happens in empyema necessitatis, for instance, in which it is of course conceded that the pus within the pleural sac does perforate the parietal layer of the pleura, even though greatly thickened From the point of view of this paper, moreover, the recognition of the presence of pus within the pleural sac communicating with a bronchus and being expectorated is, of course, far more important than the question whether the primary source of this pus be pleural or pulmonary Therefore, from this point of view it might be well to modify the definition of pleural vomicæ to be a collection of pus within the pleura communicating through a bronchus and being expectorated, with this definition the primary source of pus might be pulmonary, pleural or in the abdominal cavity

PROGNATHISM, WITH OPERATIVE TREATMENT *

WILLIAM M. HARSHA, M.D
CHICAGO

In the consideration of this subject I wish to distinguish between racial prognathism and pathologic types as illustrated by the case reported Evolution is presumed to have been from the prognathous or forward-jawed type to the orthognathous or straight face Mongolian or Caucasian type The contraction from the prognathous jaws to the orthognathous has been a factor in the production of the irregularities of dentition so common in the higher races Figure 1, shown through the courtesy of Professor Starr, represents a Taruscan Indian girl (Mexico) illustrating a racial type With the occurrence of the recession of both jaws the teeth are crowded together

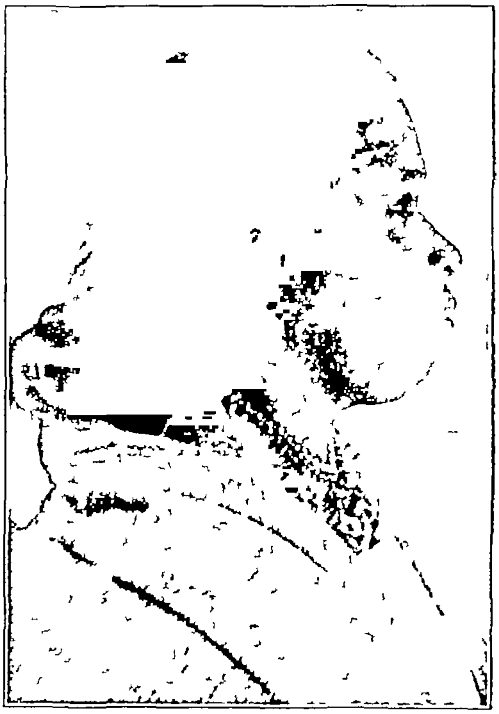

Fig 1—Taruscan Indian girl showing (racial) prognathism (Copyright by Frederick Starr)

In the case of prognathism which is the subject of this report, only the lower jaw projects and therefore the occlusion of the teeth is very imperfect (Figs 2 and 3) The incisal edges of the upper central incisors were five-eighths of an inch posterior to the incisal edge of the lower central incisors on one side and three quarters of an inch on the other There was also an overdevelopment of the mental portion of the mandible, and almost complete absence of the angle between the body and the ramus of the jaw All the lower teeth were inclined sharply toward the tongue Dental and labial sounds were inhibited There was a marked thickening of the lower lip, and a depression of the upper, with depressed alæ nas

This pathologic prognathism stands in sharp contrast to the racial type because of the malocclusion faults of alignment and overdevelopment of the mental process The occlusion and alignment of teeth in the types of race prognathism are normal, even better than the average in the higher races (Fig 4)

---

* Read in the Se[illegible] of the [illegible]dical Association at [illegible] City June 10

ETIOLOGY AND EMBRYOLOGY

Nothing valid can be suggested as to the method of production of this deformity, except error or defect in development The mandible develops from the first branchial arch, which has previously divided into a lower mandibular and an upper maxillary process In this mandibular process appears what is known as Meckel s cartilage, which is straight and rod-like, extending from the periotic capsule or site of the internal ear, to the distal part of the mandibular process

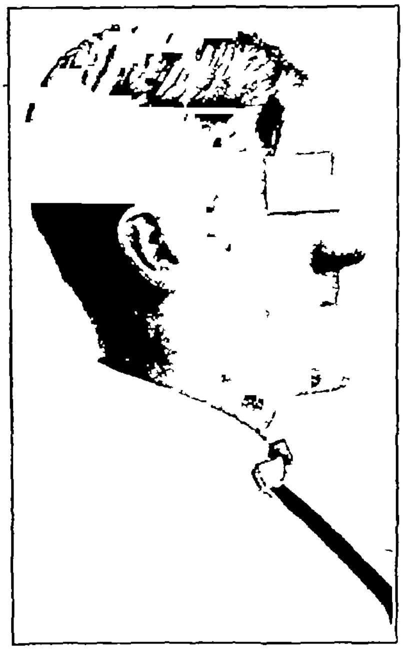

Fig 2 —Case of pathologic prognathism protrusion of lower jaw

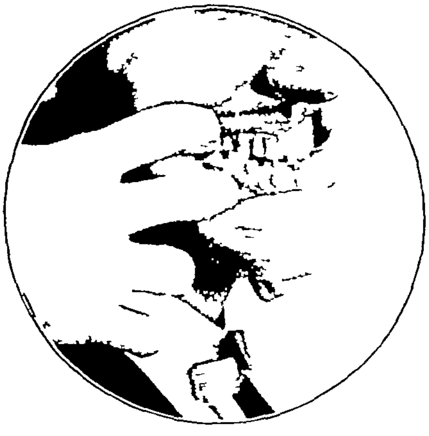

Fig 3 —Pathologic type showing faulty alignment and malocclusion

The absence of a proper angle in the case which I report suggests this defective development. The absence of the third molars which never erupted is further evidence that it is not a reversion of type, as in racial types the full number of teeth is found, and Bertillon and Fontan have even observed an extra (fourth) molar in one of the New Caledonian races

The diagnosis will require only the exclusion of an old forward dislocation of the lower jaw, with restored motion This differentiation can be done by physical examination and verified by *x*-ray

Indications for operation are

1 Inability to secure through orthodontic measures a sufficient occlusion of the teeth

2 Marked deformity because of overdevelopment of the mental portion of the mandible with malocclusion

3 Development of the mandible in a straight course, and consequent absence of a proper angle of the body of the jaw with the ramus, preventing proper occlusion.

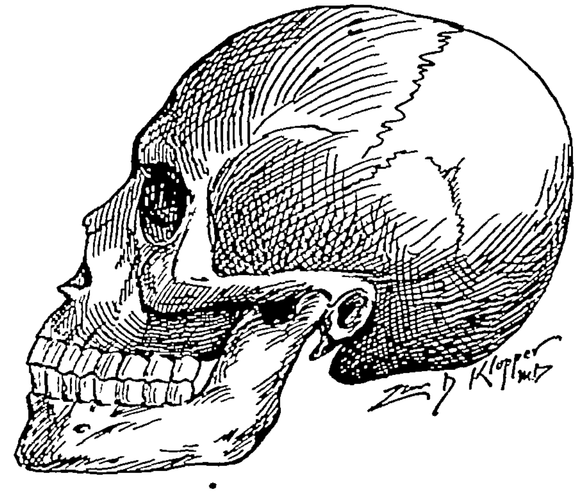

Fig 4 —Occlusion and alignment of the teeth in racial type

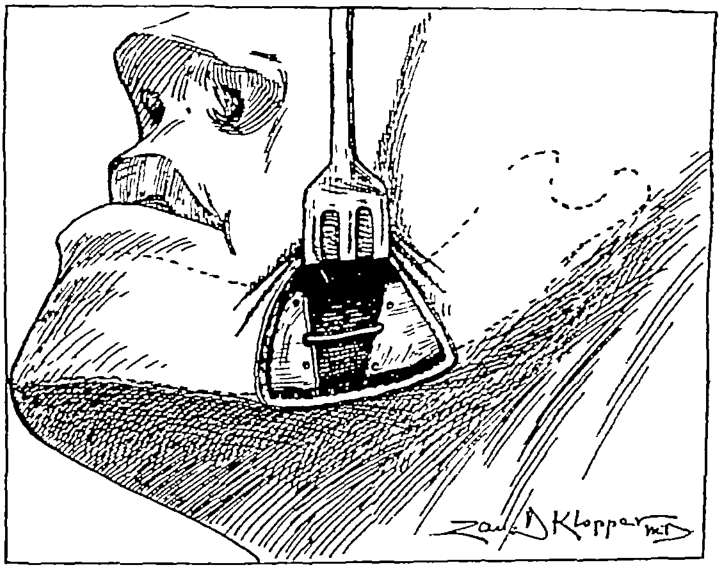

Fig 5 —Space after removal of a section to permit proper articulation.

TREATMENT

Much can be done to prevent the deformity by orthodontic measures during the early years in the way of correcting the occlusion and alignment After maturity the same means may aid in restoring alignment of the teeth and correcting the arches preliminary to operation

The first surgical treatment of which I find record is that of Hullihen of Wheeling, W Va, in 1848[1] Dr E P Blair of St Louis, on the recommendation of

---

[1] Babcock Items of Interest, xxxii 442.

Dr Angle of that city did resection between the second bicuspid and first molar in 1897 Infection delayed healing Later operations of this kind were done with the reported loss of the jaw in one case W W Babcock of Philadelphia has in later years done several operations, resecting a portion of the ramus of the jaw with successful results Dr Max Ballin of Detroit, in 1907, did a double resection between the cuspids and molars with good results, secured by extra-oral operation

The operation here reported was done with a view to secure occlusion, to correct the angle and to effect the best cosmetic result Because of the length of the mandible and the absence of the last molars, there was room at the site of the angle for resection This site for the operation seems best adapted for restoration of the proper angle which in most of these cases is lacking Estimation of the size and shape of the fragment was made from the *x*-ray plate, and models kindly made for me by Dr Joseph Eisenstaedt

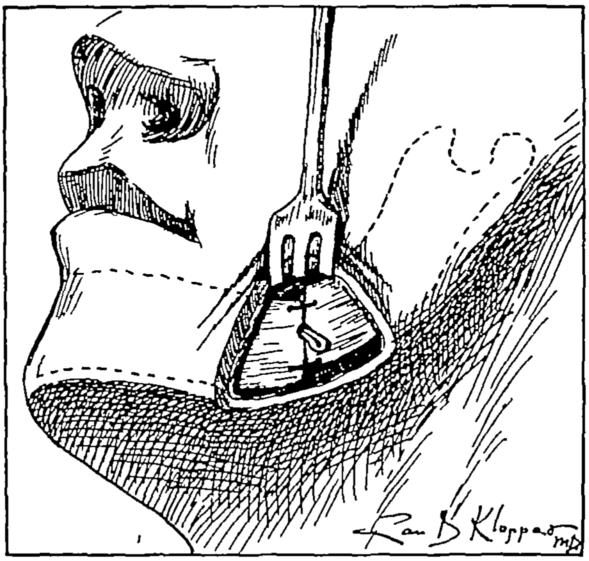

Fig 6 —Fragments wired.

REPORT OF OPERATION

Operation—Five eighths inch on one side and three-fourths inch on the other were resected through a 2 inch incision along the lower border of the jaw on each side (Fig 5) This was easily done with bone cutting forceps When the inferior dental nerve was reached, it was held out of the way by a ligature, while the upper portion was cut away The fragment was rhomboid in shape with the base above The ends of bone were fastened together, each with two wires (Fig 6) Slight mobility was permitted so that the ends might be moved upward or downward, as required, to adjust the upper and lower teeth, which were wired together by Dr Eisenstaedt by the method of Dr T L Gilmer The wound healed by primary union Before bony union had taken place, the patient was called home because of serious illness in his family and further supervision was impossible The slight immobility planned for advantage proved to be a disadvantage when the patient was out of reach The wire splints were removed before union was complete, with the result that the distal fragments were displaced upward, and it was necessary to have two molars extracted

Result—In a communication the patient says he can now talk and masticate well and that his appearance is greatly improved (Fig 7) He admits that a better result could have been secured if he had remained under treatment a sufficient time

ADVANTAGES

The advantage of extra-oral operation is obvious The selection of the site posterior to the molars is the best for correction of the angle which is desirable in almost all cases, while at this point submucous resection is easier than either anterior or posterior resection In case there is lack of room back of the teeth the last molar can be extracted and time allowed for healing over before operation, so as to make submucous resection possible

I wish to acknowledge my obligation to Dr Joseph Eisenstaedt for his valuable aid in the case along dental lines

31 North State Street

ABSTRACT OF DISCUSSION

Dr E S Talbot, Chicago I should say that this condition was an atavism of the lower jaw which returned to the original type because of an unstable nervous system of the father and mother These conditions are not uncommon when one side of the jaw is longer than the other The appearance of this picture leads me to believe that this was a very unstable individual, as far as the nervous system was concerned I can say very little about the operation because I have never performed it in this way Dr Harsha has performed it successfully to all appearances, and perhaps a little differently from the technic which Dr Babcock presented to our Section a year or two ago This will go down no doubt in history as one of the first cases in which the operation was performed in this location.

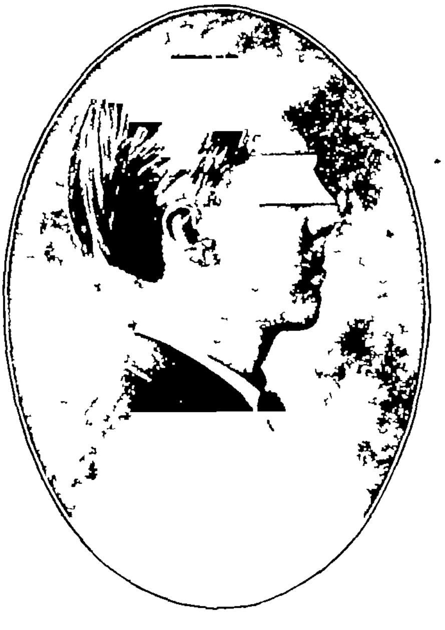

Fig 7 —Profile of patient after recovery

Dr. W Wayne Babcock, Philadelphia One of the great handicaps in operations of this type is the fact that the upper jaw is badly developed If one could develop the upper jaw properly, the need for extensive resection of the lower jaw would not be so great The tendency in many cases is to injure the patient's appearance by operation Some operations take from the individual the firmness of character of the rather large lower jaw There are difficulties in enlarging the upper jaw, but, of course, a great deal could be done for the patients if they went to a capable orthodontist early in life It remains, however, after a certain degree of fixation has occurred, for the surgeon or dentist to get, not a perfect result, but [illegible] that w[illegible] the [illegible] and the powers [illegible] the body of t[illegible] case worked very well The difficulty, of course, in attacking the body of the jaw, is that we interfere with the teeth, and if the teeth are extracted and the jaw at once resected, the compound fracture into the mouth adds much to the danger of later sepsis A suggested improvement is to remove one or two teeth and then, after healing occurs to do a submucous resection of the jaw from the under side One need not fear to resect or to destroy the inferior dental nerve The nerve rapidly regenerates, the teeth maintain their function and nutrition and the tissues their vascularity, unless infection spreads through the jaw, when necrosis is followed by menace to the teeth, as well as to the entire bony structure.

After the report of a somewhat similar case before this Section some years ago I had occasion to use a steel splint instead of wiring, and I was impressed by its value I have applied Lane plates after resection or division of the jaw, and in one instance I screwed an angular ramus made of steel to the body of the jaw below the angle so as to form a false ramus and joint This worked very well, but a rough projection at the angle finally worked through the overlying skin The steel was not expelled and the patient wore this artificial ramus of steel with a point protruding for about four months without any inconvenience except a slight discharge from the perforation Of course, during the healing process it is wise to have an additional support

Dr. Thomas L Gilmer, Chicago There is certainly little known about the etiology of prognathism of the mandible, but it is known that inheritance has much to do with it, I know many children with prognathism of the lower jaw which can be traced to heredity The operation is worth while for cosmetic purposes, if for no other, and, as Dr Babcock has said, it is not impossible that the results cosmetically may be worse than the deformity, but it does not seem to me that this should often be the case

The pictures exhibited by Dr Harsha do not show that the mandible is much too long, but rather that the maxilla is too short It may have lengthened somewhat on account of the occlusion of the teeth

I do not think that it makes very much difference whether the nerve in the mandible is severed I have done many operations for removal of the inferior dental nerve, also of the second branch, in cases of tic douloureux, and I have never seen a dead pulp in a tooth as a result I hope that some time it will be known what changes if any occur in the pulps of teeth after resection of the nerve Dr Babcock spoke of the advisability of cutting the bone at the angle If the operation is done in this locality there is less danger of entering the oral cavity, since the thickness of soft tissues overlying the bone in the mouth is greater here than further forward

I have used the Lane plates in fractures of the mandible, but if we can get along without drilling into the bone we lessen the possibility of bone and other infection By wiring the lower to the upper teeth we use the upper teeth as a splint which holds the parts rigidly The only objection to this method is the fixed closure of the jaw Any technic is good which in the experience of the operator succeeds

Dr. G V I Brown, Milwaukee, Wis This Section has had the opportunity to consider two methods which represent the newest and best surgical procedures for resection of the mandible for the purpose of improving tooth occlusion and facial conditions Some of us at least have felt rather strongly about the unfortunate publicity that has been given the earlier attempts to perform the operation to which Dr Harsha referred, in the course of which at least several important surgical principles were needlessly violated Dr Babcock's method as he explained it to us, and as since published, judged from a surgical standpoint appears to be perfect for resection at the particular point he selected, this also may be said of Dr Harsha's method The point which Dr Babcock raised, which was emphasized by Dr Gilmer, is really the vital question In some conditions such an operation may be called for, but they seldom occur Most of the patients whose jaws present the picture exhibited by Dr Harsha are persons who are being deprived of some very vital necessities, and it is vastly more important that these people be given general relief through better respiration, by spreading the upper arch in addition to facial improvement, than that we improve their appearance alone by the reduction of the lower jaw If one examines the palates in such cases it will be found that most of those with upper arches shaped like that of this patient and with palatal vaults similarly formed, are persons in whom there has been a distinct loss through arrested development of the upper maxillæ This condition usually affects very vitally both nasal form and structure, and less directly, but almost certainly general nervous conditions also Such persons are commonly highly nervous, and many times have nervous habits of one kind or another that are closely akin to chorea or similar affections I think these corrective possibilities should be considered first and surgical procedures afterward, but if it finally be decided that resection is necessary, I am satisfied that we can do no better than to follow either Dr Babcock's or Dr Harsha's method

Dr. A J Flanagan, Springfield, Mass I would like to find out the length of time that such cases as these have been under observation For instance, some have spoken of the inferior dental nerve not being affected in these operations, is there any instance of some years' standing in which the inferior dental nerve has been removed and a record kept of the conditions which follow? Has there been a case of which a record has been kept for more than fifteen years, in which there has been no paralysis, no nephritis and no symptom of conditions such as Dr Brown spoke of? Is there any record of positive results of never having any trouble because of the removal of the inferior dental nerve?

Dr. T L Gilmer, Chicago I have one case that I know positively is of fifteen years' standing, in which I removed the second branch of the fifth nerve, going underneath the eye to do so, and the pulps of all the teeth are still alive

Dr J Lowe Young, New York Study of Dr Harsha's models shows that it is impossible to put these plaster teeth in occlusion The best that can be hoped for from this operation, if these models are accurate, is the cosmetic effect It is impossible, I think, for any man to get a good chewing apparatus with these teeth by any surgical operation, such as has been done here There are cases in which it is advisable to perform surgical operations, I have had a few cases in my practice, but they were in adult life I am not in favor of treating adults orthodontically, because the orthodontic trouble really goes back to bone development Bone development is very slow at any time, and particularly so in adult life, and I do not want to attempt the treatment of a case without the possibility of seeing the finish I would like to suggest, however, to the surgeons to whom these cases come, to be exceedingly careful of the conditions Accurate impressions should be taken and plaster models should be made to determine if proper occlusion can be obtained in the place that the incision is to be made In Dr Harsha's case the wiring of the teeth together does not help very materially to hold the front portion of the mandible in place, because the incision is back of the last molar tooth This also applies to Dr Babcock's operation, that is why I think he had to use the steel plates in one of the cases to which he referred If it were deemed practical to make the incision further forward, then I think it would be very much easier to get fixation of the part, which, of course, would facilitate the final union of the bone

Dr W M. Harsha, Chicago The contraction of the upper arch was from side to side, the upper incisors did not recede but were nearly normal in direction The palate was high It is known that afferent nerves regenerate much more readily (from the peripheral side) than the efferent I have frequently resected the inferior dental nerve with apparently too early regeneration, and with no appreciable injury to the teeth. Resection at the point which Dr Babcock selects does not, in my opinion, restore the proper angle, as is possible at the point where I did it In my case the line of the mandible was almost straight The Lane plates could be used on the jaw, but in compound fracture, for instance they would generally have to be emoved, while in simple fractures union is so prompt, that for the short time required apposition can be maintained by more simple means

BLENNORRHAGIC KERATOSIS *

BURCHARD H ROARK, S B, M D
SPOKANE, WASH

Last June I reported to the Spokane County Medical Society a case of an unusual keratosis attending gonorrhea, which I now report as a typical case of blennorrhagic keratosis Except for the report of this disease by Simpson,[1] I should not be able at this time to classify this case properly It is, I believe, the second case reported in America, and the twenty-second case recorded in medical literature It is of special interest because it is probably a gonorrheal skin disease

History—The patient, W B, aged 26, American of Welsh parentage, with negative family history, and unimportant personal history except for two attacks of gonorrhea, came under my care May 9, 1912, suffering with an acute gonorrhea and with horny like, papular eruptions on the soles of both feet. His gonorrheal infection began two weeks previous to my seeing him, and had been running rather a mild course until about the tenth day of the gonorrhea, when he noticed about forty nodular patches on the soles of both feet, somewhat more on the left than on the right foot, which were intensely painful and made walking impossible, and his left ankle became greatly swollen, painful and tender

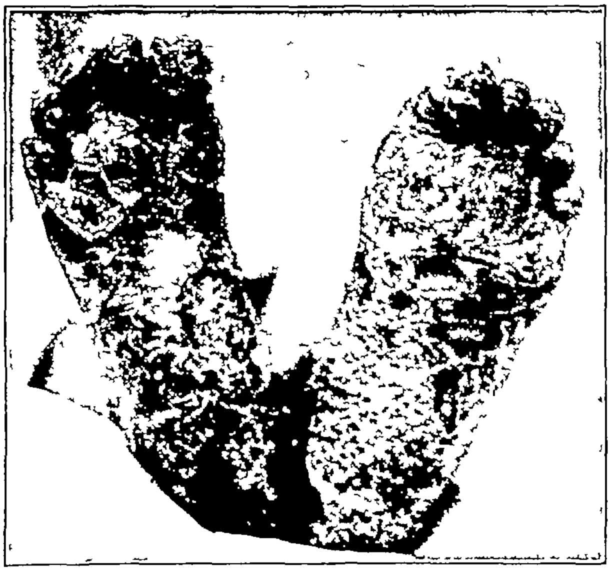

Fig 1—Appearance of the soles of the feet in a case of blennorrhagic keratosis

Examination—I found the patient with temperature of 101, pulse 100, and his appearance one of moderate toxemia He was suffering with a typical gonorrheal urethritis, a gonorrheal arthritis, undoubtedly of the left ankle, and the keratoid nodules mentioned These were characterized by a greatly thickened epidermis beneath which was a disk shaped gelatinous like mass of secretion which could be picked out without breaking or crumbling, of the consistence of putty, yellowish gray in color When the keratoid formation and the disk shaped mass were removed, a moist pinkish base remained, appearing as new skin These nodules measured about 2 or 3 cm in diameter, were round, and raised about 1 cm above the normal surface In this condition he was sent to the Sacred Heart Hospital where he remained under observation for four and one-half months His temperature ranged from 99.5 in the mornings to 100 or 101 in the afternoons At no time did his temperature exceed 101 8, though it sometimes varied greatly at different times of the day His pulse varied from 56 to 120, going up and down with the temperature

Course—The crusty horn like nodules multiplied on the soles of the feet until there was excoriation of large areas of the epidermis (Fig 1) The toe nails soon showed great thickening under their tips, becoming separated from their base, as this keratosis extended back under the nails, and a yellowish gray transparent secretion escaped from under the nails Within three weeks all of his toe nails came off leaving a pinkish tender nail bed exposed This bed would soon be covered (within two or three days) with a thick yellow crust which, when removed, would be followed with another similar formation Meanwhile, over the dorsum of the feet and about the ankles there appeared little papular eruptions about the size of the head of a pin, containing under the thickening epidermis a little drop of yellow mucoid secretion Gradually for several days these papules enlarged until waxy, horn like nodules appeared as first described, giving the feet and ankles a loathsome appearance If the top were pinched off and the yellow wax removed, the epidermal thickening continued and the result was the characteristic round cone like nodule, 'roughly resembling" as Simpson says, "in consistence and appearance the pustules of small pox" Except where two or more of these patches coalesced, they were invariably round and cone shaped (Fig 1)

The patient's finger nails began the same process of exfoliation as occurred with the toe nails, the nails of the right thumb and middle finger coming off entirely, while the index finger nail on the right hand and the thumb and little finger nails on the left hand showed thickening under their tips and separated about half way back, at which point the process stopped with the general improvement of the patient.

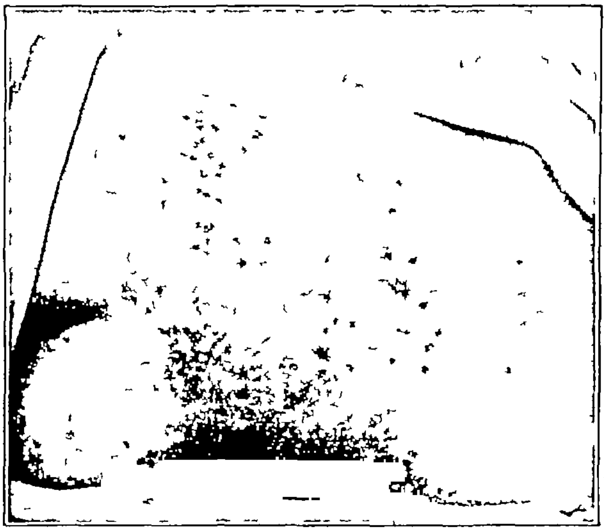

Fig 2.—The back of the patient

Meanwhile, within six weeks after the patient entered the hospital, the same crust like nodules appeared on other parts of the body eight on the scalp, two on the left arm, many covering the right thumb and middle finger, one on the dorsum of the left ring finger, one over the sternum, three large ones on the front of the left knee, a few along the outer part of both thighs and many over the lower back (Fig 2)

A severe balanitis persisted for over two months

In addition to the arthritis of the left ankle joint, arthritis developed in both knees, left hip, second joint of right middle finger, right elbow and slightly in both shoulders

May 14, Wassermann test negative Dr M M Patton

Smears from the little drop of yellow wax in the early formation showed no microorganisms One blood serum tube culture showed, after three days a watery growth which was a pure culture of a Gram negative diplococcus but appeared too fat for the Neisser diplococcus and not similar in cultural peculiarities, growing readily [illegible] potato for example I am inclined to attach no significance to this growth in the absence of any other results from smears or cultures, and account for it as a contamination, but relate its appearance because of a possible value it may have in further study of cases

[1] Simpson Frank E. THE JOURNAL A M A. Aug 24 1012 p 607

Treatment—Beginning May 28, an injection of gonorrheal mixed vaccine (Cutter) was given every second day for sixteen days, beginning with 25 million gonococci and increasing to 250 million During all this time the condition of the patient was grave, and because many who saw the patient regarded the case as possibly one of syphilis, I followed the eight injections of gonorrheal mixed vaccine, in spite of the negative Wassermann, with 0 6 gm salvarsan, administered intravenously Following this, while the patient was at his worst, Dr M M. Patton made an autogenous vaccine from cultures from the feet (containing *Staphlococcus aureus* and *S albus*) and administered seven doses altogether

Local treatments were superfluous, except in so far as mixed infection might be excluded The isolated nodule seemed to do better if left absolutely alone

Finally, along the first ten days of August, after the outlook began to appear hopeless, the patient began to improve and made a rather rapid convalescence I believe that the administration of the gonorrheal mixed vaccine was of benefit, at least the joint involvement improved following its use, though the skin lesions did not seem to improve, possibly because the feet at this time began to show evidence of ordinary pus infection For this the autogenous vaccine produced by Dr Patton may have done more good than we were inclined to believe

Internal medication was symptomatic and unimportant

At present, Oct. 24, the patient is progressing nicely The exfoliated nails are returning and the skin is smooth All joints are normal except that the right middle finger and the big toe of the right foot remain flexed, and the shoulders are a little stiff The left foot swells after walking, but only slightly The patient's weight is 102, and during the last twenty days he has gained about 1 pound a day His usual weight is 125

The patient relates that in June of 1908 while suffering with acute gonorrhea and gonorrheal rheumatism he had many crusty horny like nodules on the soles of his feet which disappeared with his convalescence from the gonorrheal trouble In the absence of any other etiologic factor, I feel that we are justified in considering this peculiar condition a gonorrheal skin disease

EXOPHTHALMOS IN SCURVY*

L. R. DEBUYS, M D
Assistant Professor of Diseases of Children in the Medical Department of the Tulane University of Louisiana Junior Pediatrist of the Touro Infirmary Pediatrist at the Presbyterian Hospital Visiting Physician Diseases of Children at the Charity Hospital
NEW ORLEANS

A review of the literature on the condition of the protrusion of the eye in connection with scurvy shows that the terms "proptosis" and "exophthalmos," which are synonyms, are used to designate varying degrees of the protrusion Proptosis is the more commonly used, and specifies the condition when not extreme, whereas exophthalmos is the term always employed to signify the extreme protrusion of the eyeball

The committee of the American Pediatric Society in its "Collective Investigation of Infantile Scurvy in North America," in 379 cases reported that swelling and protrusion of the eye was noted in forty instances[1] Heubner,[2] in his collection of sixty-five cases, states that the orbit was involved four times, and Jacobi,[3] in forty cases, four times In the foregoing cases it is not stated whether the protrusion of the eye was slight, or whether there was a decided exophthalmos In view of this fact, and also becauses cases of exophthalmos in scurvy have been rarely reported, it is reasonable to presume that had these cases been extreme, they would have been published

Text-books on the diseases of children make unimportant and subordinate mention of proptosis in some instances, and vague mention in other instances, in some text-books there is no mention at all made of the symptom In text-books and journals on the diseases of the eye, even less is to be found on the subject In only two instances[4] was it possible to find mention of orbital hemorrhage in scurvy The references in both instances are practically the same[5]

The case of Magnus, which he reported in 1878, is probably the first report of exophthalmos in scurvy Before Barlow's[6] article in 1883, on "Cases Described as Acute Rickets, Which are Probably a Combination of Scurvy and Rickets, the Scurvy being an Essential, and the Rickets a Variable Element," many cases of scurvy were reported as acute rickets A case appearing under the title of "Acute Rickets" was reported by Moller[7] in 1862, in which there was an exophthalmos In this case, because of the absence of affection of the limb bones either during life or at post-mortem, Barlow did not include it as one of scurvy in his analysis It must be said in this connection that cases have appeared in more recent years in which the diagnosis of scurvy has been made with few symptoms other than exophthalmos

The number of cases of exophthalmos in scurvy appearing in literature are very few It has been possible for me to collect reports of only thirteen cases, including my own, which are reported in full From the study of these cases, (which I have tabulated and appended to this paper,) and the literature on the subject, the following may be said

Proptosis or exophthalmos in scurvy consists in a protrusion of the eyeball from its orbit. This protrusion may be of variable degree, from slight to extreme It may occur at any time during an attack of scurvy, it is at times caused by violent fits of crying (Cohn,[8] Jacobi,[9] DeBuys) and appears suddenly, or it may be precipitated by prolonged crying (Jacobi[10]) Extreme exophthalmos is rarely seen, though protrusion of the eyeball may occur in from 6 to 11 per cent of cases of scurvy The condition may be caused by ecchymoses, into the loose areolar tissue around the orbit (Railton,[11] Fischer,[12] Carr,[13] Hutchison[14]) or the subperiosteal extravasations of blood which are seen elsewhere may be found also in the bones of the head and face (Miller,[15]

Sheffield,[16] Pfaundler and Schlossman[17]) In the instance of exophthalmos the hemorrhage takes place beneath the periosteum within the orbit, and does not interfere with the motility of the eye Barlow[18] believes that he has evidence for the conclusion that subperiosteal hemorrhage within the orbital cavity caused the exophthalmos in his cases, while Meyer[19] and Snow[20] were able to demonstrate at autopsy the presence of subperiosteal hemorrhage within the orbit in their respective cases

The exophthalmos may appear in one or both eyes, beginning in one and involving the other subsequently It comes on suddenly and causes a displacement of the eye forward, downward and outward There may be an improvement, the eye returning to its normal position, to be followed by a recurrence (Magnus,[5] DeBuys), or the eye may remain stationary, and at intervals the symptoms increase (Jacobi,[3] DeBuys) If the hemorrhage extends in front of the fascia orbitalis there may be an associated ecchymosis and suggillation, the upper lid becoming discolored and puffy, caused by the infiltration of blood into the loose connective tissue of the lids, or the exophthalmos may exist as the sole evidence of hemorrhage into the loose areolar tissue within the orbit, or of subperiosteal hemorrhage within the orbit providing the hemorrhage does not extend in front of the fascia orbitalis This symptom is usually a late manifestation in scurvy, though it has been noted as being among the earlier evidences (Schlesinger[21]), and Barlow[22] has described a case in which the exophthalmos was the only symptom of the disease

Proptosis or exophthalmos should not be confounded with the conditions more frequently found when there is actually no displacement, but the ecchymoses and suggillations are in the soft tissues in front of the eye, and hemorrhage under the conjunctiva, giving the effect of a displaced eye In these conditions the tissues may become so much involved as almost to close the eye, whereas in exophthalmos the aperture of the lids is much wider than normal and the eye is seldom completely covered by the lids

In injury of the eye producing a proptosis or exophthalmos, besides the history of the injury there are wanting the other evidences of scurvy, and the therapeutic test will clear the diagnosis

In malignancy there is not the sudden swelling, the motility of the eye is impaired in extreme cases, the evidences of scurvy are not present, and antiscorbutic treatment also has no effect

Gumma of the periosteum within the orbit may produce an exophthalmos, but the onset is very slow and gradual

Mucocele, encephalocele and hydrocephalus may give rise to a displacement of the eye, but there are enough other symptoms in these conditions to permit a differential diagnosis

Barlow[23] states that he is of the opinion that in no disease, even syphilis, is the therapeutic test of more value than in scurvy In making a therapeutic diagnosis should there be no improvement in four or five days, the diagnosis should be questioned

Within the past few months it was my good fortune to see the following case of extreme exophthalmos in a case of scurvy

REPORT OF CASE

History—T G white female aged 11 months, only child of healthy parents, appeared at my clinic at the Touro Infirmary, Nov 23 1911, because of one eye protruding almost out of its socket and because of pains in the limbs which were diagnosed as rheumatism by a physician

The baby was born at full term by a foot presentation after a prolonged labor She weighed about 4,082 gm (nearly 9 pounds) at birth Her eyes became sore shortly after birth, and she had a nasal discharge The mother nursed her exclusively on the breast for six weeks She was then given malted milk for two weeks Then, because of frequent stools, condensed milk was given She was ill with "cholera infantum" for two weeks, and was put back on malted milk, which was continued thereafter Her feedings were irregular, as was also the quantity given at each feeding At 4 months she had two teeth, and at 8 months she was able to sit alone There had never been any convulsions Aside from "cholera infantum' at 2 months, the only sickness up to the present illness was a siege of boils which continued throughout the past summer From this time on it was noticed that the baby perspired very freely, particularly about the head The present illness began about the middle of August, 1911, when her left leg was knocked on being lifted from her chair She screamed as if her leg were broken" and it began to swell She seemed to be in pain when touched, and was very cross and restless at night About one week later the parents consulted the family physician who diagnosed the condition as rheumatism It was found out later that he believed it to be syphilitic, and the baby was treated with mercury by inunction She was also given drops, persumably iodid in some form

In the latter part of August one day about five minutes after her bath, the baby cried violently The mother on going to her to investigate the cause of her crying, noticed that her right eye was protruding, and that the upper and lower lids were discolored and swollen These symptoms remained the same for three or four days, and then became better gradually for three or four days, at the end of which time the eye was apparently back in its normal place so that it could not be noticed that it had been pushed out Three weeks after this it again protruded, but the discoloration was not so marked as with the first attack The discoloration remained for about one week The exophthalmos continued for about one week, but improved slightly during that time The protrusion was not so pronounced as on the first occasion, nor was the improvement so marked It then suddenly protruded again much more than on the other occasions, and remained out until it was seen by me three weeks later The mother stated that there was no discoloration the third time, and that the protrusion was increasing very slowly until I saw it. The patient's eye was not completely closed during sleep The second and third occasions of protrusion of the eye were at night, the displacement being noticed in the morning

The baby had four upper incisors and two lower central incisors when her leg was hit Her gums were red and swollen at the time of the first exophthalmos Three weeks later they were bluish red The baby seemed to be in much pain, cried a great deal and was irritable At night she was restless There had been no fever The appetite was poor and at times there was vomiting of a greenish substance The stools were not noticed as being different from her normal stools The urine was brown since before the first exophthalmos, was plentiful, and stained the napkins On one occasion after the second exophthalmos, when the baby vomited, blood came from her nose Other than these there were no hemorrhages noticed

Examination.—The child was poorly developed and poorly nourished anemic, much emaciated, 65 cm (25¼ inches) long weighing 5,132 gm (a little over 11 [illegible]) She was anemic, and the mucous [illegible] were [illegible] ght eye

protruded almost out of its socket, being pushed forward, outward and downward There was no pulsation The eyelids were clear, but apparently puffy The movements of the eye were not impaired, and the sclera and conjunctiva were normal The baby lay with her legs everted and flexed, and there was apparently no muscular power There was no inclination to move the arms The skin was clear with the exception of the right leg, on which there were two ecchymotic spots Over the thighs and legs, which were very much swollen, the skin was tense and glossy The thorax was flattened anteroposteriorly, the sternum was depressed and the abdomen distended *On being moved for examination the baby cried* as if in much pain The head was rather square and the anterior fontanel was opened and depressed The sutures were not closed There was costal beading and slight kyphosis, but the epiphyses were normal *Examination of the abdomen* showed it to be soft, with walls flabby, but liver normal and *spleen not felt* Examination of the heart and lungs was negative The arms, legs and back apparently lacked muscular power, though no attempt at determining the muscular power was made because movement was accompanied with great pain The thighs were much swollen, the deeper structures especially so The shafts of the femora were firm and thickened for almost their entire length The same condition existed in both legs, the swelling being mostly about the lower ends of the tibias The joints were normal There was pain on moving the arms, in fact, touching the patient almost anywhere seemed to cause pain.

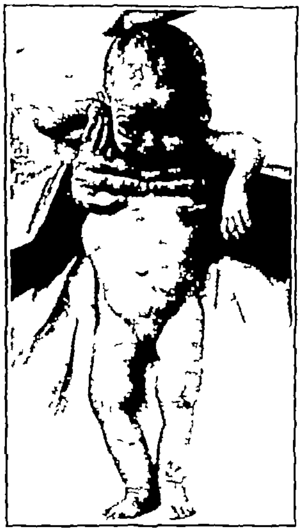

Fig 1 —A photograph taken Nov 23 1911 (before treatment was begun), showing the exophthalmos with the forward and outward displacement The peculiarly flattened chest may be noticed, and the angle or bending of the ribs The thighs and legs particularly on the right side are much swollen The feet also are swollen The ecchymotic spots on the right leg can be seen

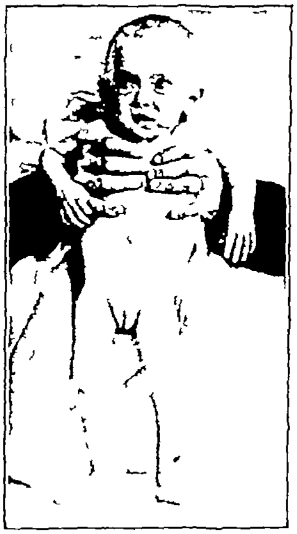

Fig 2.—A photograph taken Dec. 5 1911 (after treatment was begun) shows improvement in the exophthalmos and in the child s general condition The expression of pain has disappeared. The state of nourishment is better This can also be seen by comparing the abdomen with Figure 1 Improvement in the legs can readily be seen *also disappearance* of the ecchymotic spots Swellings of the feet also have disappeared.

The respirations were normal, pulse, 164, temperature, 38.8 C (101 8 F) by rectum. The gums were reddened, spongy and swollen She was referred *for examination* of her eyes Dr M Feingold reported that both fundi were normal, and that there was a tumor of some sort pressing within the orbit in the upper half and inner side The examination of the nose was negative, there being no evidence of acute or chronic inflammation

Treatment and Subsequent Course—The mother was requested to take the child to the radiologist for skiagrams, but she did not do so, and was lost sight of for a few days, even before the blood and urine could be examined. Twelve days elapsed before the patient was seen again In the belief that an interesting case was about to be lost sight of a special endeavor was made to complete the examinations, with the result that skiagrams, photographs and examinations of the blood were made Owing to the inability of the mother to secure the urine, an examination of it was not made, but the mother stated that the urine was no longer brownish, it having cleared entirely two or three days after the first visit On the occasion of the first visit, the mother was instructed to give the baby a teaspoonful of orange juice every four hours, proper instruction regarding feeding was *also given* When the patient was seen the second time the exophthalmos was much improved, the eye having almost returned to its normal position, the legs were greatly reduced in size, and were not very painful The ecchymotic spots *on the leg had disappeared, the baby was much more* quiet and less irritable, and there was hardly any pain on being handled This interesting improvement was attributed solely to the use of orange juice, because the mother had not changed the diet as she had been *instructed* The *photographs* (Figs 1, 2 and 3) before and after twelve days of treatment also show the improvement In spite of these marked changes, the skiagrams taken twelve days after the treatment was instituted (Figs 5, 6 and 7) show unmistakable evidence of scurvy

The result of the blood examination showed hemoglobin, 65 per cent, red blood corpuscles, 3,920,000, white blood corpuscles, 4,950, neutrophils, 42 per cent, small lymphocytes, 50 per cent, large mononuclears, 5 per cent, eosinophils, 3 per cent Coagulation time was between five and one half and six minutes (Wright)

It developed that the reason the patient was not placed on the prescribed diet was for fear of the parents' incurring the displeasure of their society physician, who had continued the usual diet The parents consented to allow further observations of the patient to be made in appreciation of the improvement following the antiscorbutic treatment

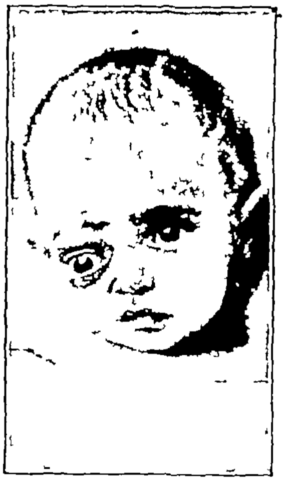

Fig 3 —A photograph taken Nov 23 1911 (before treatment was begun) allows a better study of the exophthalmos. Its displacement downward outward and forward can be seen The facial expression also can be studied *more closely*

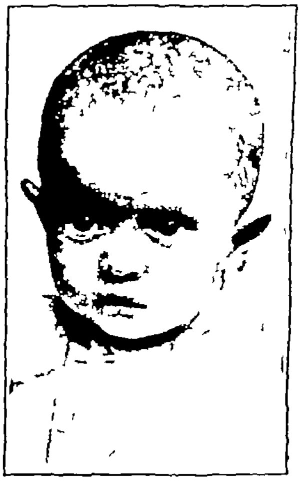

Fig 4 —A photograph taken April 15 1912 before the leg had thoroughly assumed its normal position

The patient was again seen *April* 9 She was *15 months* old, and with her clothes on weighed 6,987 gm (nearly 10¼ pounds) The anterior fontanel was open and measured 5 cm by 5 cm (nearly 2 inches) She was pale and sallow, had seven teeth and could sit up, but could not walk There had been no further trouble with her eye, and no return of any other symptoms of scurvy The orange juice had been continuously given, the diet remaining the same It is interesting to note that after the first marked change following the use of orange juice, *the further improvement had* been very slow, probably because the diet had not also been changed This was shown by subsequent photographs and skiagrams (Figs 4 and 8) and also by the examination of the eye, there still remaining a slight exophthalmos· The report of Dr Feingold was as follows palpebral opening narrowed, difference of about 1 mm, and probably shorter, with Hertel *exophthalmometer unsatisfactory examination*, exophthalmos of about 1 5 mm on right side, lower half of right cornea more covered than in the left eye, upper lid also covering more of cornea in the right than in the left eye, pupillary reaction and motility perfect

A series of examinations was made again on this visit resulting in some further improvement. The blood examination showed hemoglobin, 90 per cent red blood corpuscles, 4,230,000, white blood corpuscles, 6,250, neutrophils, 44 per cent , small lymphocytes, 50 per cent , large mononuclears, 6 per cent The coagulation time was between three and three and one half minutes (Wright) Wassermann and von Pirquet reactions were negative

DIAGNOSIS OF CASE AS SCURVY

The clinical picture of the case is typically that of scurvy *Certain conditions, however, must be excluded* because they present some of the symptoms found in this case

Rheumatism was excluded because it is a rare condition at this age, and also because when rheumatism is found before the fourth or fifth year it rarely manifests itself by swelling of the joints, and when rheumatism does involve them there are evidences of inflammation In this case not the joints but the shafts were involved, and there was no redness or evidence of inflammation

Osteomyelitis was excluded because it is a condition in which there are high fever, abscess, and usually one bone involved

Sarcoma was excluded because it does not involve as a rule more than one bone, is progressive in its course, and because antiscorbutic treatment has no effect on it

Syphilis was excluded because the pseudoparalysis in lues appears at a much earlier age and is one symptom of a condition in which there are many other manifestations Again, had the condition been syphilis the liver and spleen would have been enlarged and the antisyphilitic medication used should have improved the condition in over two weeks' treatment instead of aggravating it On the other hand, the improvement under the influence of orange-juice was a therapeutic diagnosis sufficient to remove all doubt The negative Wassermann may have been produced by a prolonged course of antisyphilitic treatment, but the history does not warrant the suspicion of syphilis

In confirmation of the diagnosis against the foregoing conditions, the skiagrams offer positive proof of their non-existence

Anterior poliomyelitis was excluded because there was a negative history for infantile paralysis, and because of the symptoms of scurvy being characteristic In doubtful cases an electrical reaction is diagnostic This was neither advisable nor necessary in this case

Purpura could not be considered because there is an absence of the history of improper feeding in purpura, and it is not accompanied with swelling of bones from hemorrhage with accompanying pain

That medication had no influence on the production of the condition is shown in the history, as the disease began before the drugs were given, and the improvement was marked before they were discontinued

In rickets there are no ecchymoses, no pain, no spongy gums and also the ends of the long bones are involved It must be remembered however, that for a long time the two conditions were considered together until Barlow's original article Moreover, rickets and scurvy are frequently seen together probably because the diet that produces scurvy may be also an etiologic factor in the production of rickets

The exophthalmos might have necessitated differentiation from malignancy and trauma, but the other evidences of scurvy and the diagnostic significance earlier considered in this paper readily exclude both

Finally, the therapeutic test of the diagnosis establishes the case as one of scurvy

I wish to express my thanks to Dr M. Feingold for the examinations of the eye Dr A. D Henriques for the skiagraphic work, and Dr C C Bass for the laboratory examinations

1776 State Street

ABSTRACT OF DISCUSSION

Dr H M McClanahan, Omaha I see about four cases of scurvy a year in consultation In three out of four of my cases the diagnosis had not been made Out of ten cases of which I have records, in four the first symptom was hematuria In three of these a diagnosis of scurvy was made on the hematuria as the only symptom

Dr W W Butterworth, New Orleans In spite of all our education along certain lines we have not educated the physician to differentiate between so called rheumatism and scurvy in the young infant It seems that it is still possible to make this mistake

Dr. L R. DeBuys, New Orleans I believe the English pay more attention to the examination of urine than we do As I understand it, in some institutions a routine examination is made consequently they find blood in the urine more frequently and are thereby better able to recognize those cases of scurvy in which the bloody urine is an early symptom In scurvy the lower extremities are more commonly involved than the upper Rheumatism seems to be the condition most often confounded with scurvy, and this mistake in the diagnosis is the one most frequently made

In one of my radiographs a condition can be seen which I have not been able to find before the zones of proliferation in the bones Most radiographs show the early conditions of scurvy which are important for diagnostic purposes, but I have seen no other radiographs which show these changes

OCCUPATIONAL SKIN DISEASES [*]

JOHN A FORDYCE, MD
Professor of Dermatology and Syphilology University and Bellevue Hospital Medical College
NEW YORK

With the exception of certain well-defined types, occupation dermatoses as a class have not, in this country at least received the attention they merit While every dermatologic clinic numbers among its applicants each year many patients in whom occupation has a direct or indirect bearing on the causation of their eruption it is difficult, owing to lack of systematic investigation, to give a definite idea as to the prevalence of skin affections in the various trades At my own clinic at the University and Bellevue Hospital Medical College about 2 per cent of the total number of new cases for 1911 constituted occupation dermatoses The great majority of these were of the type known as trade eczemas, and while many cases yield readily to treatment and proper preventive measures, others constitute a serious inconvenience from an economic point of view, sometimes necessitating a complete cessation from work or a change of occupation.

---

[*] Read in the Symposium on Industrial Diseases in the Section on Preventive Medicine and Public Health of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912.

Cutaneous vulnerability is more or less an individual peculiarity, for while there are persons who are so sensitive to an irritant — physical, chemical, thermal or actinic — that they react after a short exposure or contact by an acute dermatitis, others remain entirely unaffected. Occasionally such persons exhibit so high a degree of sensitiveness that instead of their acquiring an immunity, an increasing susceptibility is established. Fortunately these cases are not very common, and workers who are subjected to continuous injury usually do not develop lesions until after a longer time, either from the summation effects of the irritant or because the resistance of the skin has been gradually undermined.

After such a cutaneous outbreak there is frequently a tendency to acute exacerbations at regular intervals or when the occupation is resumed. These eruptions may then persist for years. While the skin both anatomically and physiologically is endowed with a relative amount of protection against the action of irritant substances, by reason of its exposure it is subjected to injuries of every description and these may lay the foundation for a subsequent eruption. In addition, there are other contributing factors, such as a "special susceptibility," a delicate skin or one presenting some congenital anomaly, as excessive dryness or ichthyosis, impaired gastro-intestinal, hepatic or renal function, a depressed state of health, neglected hygiene of the skin, or its lowered resistance because of a preexisting eruption.

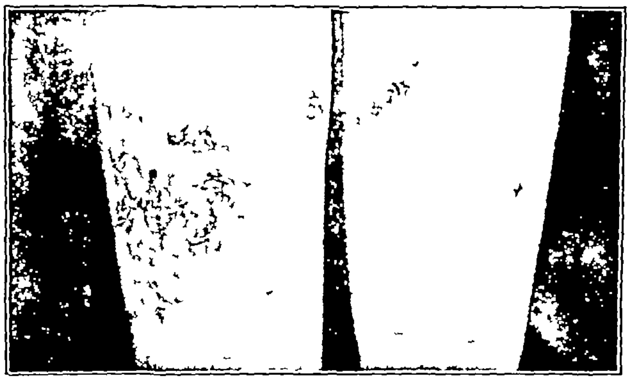

Fig. 1.—Erythema induratum (Bazin's disease).

The same etiologic factor is often found operative in both allied and unrelated trades owing to similar conditions under which the work is done, when, for example, men or women are exposed to excessively dry or moist heat. Such an atmosphere leads to congestion and interference with the normal activity of the skin which is followed by various inflammatory processes and sweat-eruptions like prickly heat. These affections are seen in cooks, stokers, firemen, foundry-workers, etc. A warm, moist medium such as laundresses work in sometimes produces a cystic condition of the sweat-ducts of the middle third of the face, known as hydrocystoma. Cold, by favoring the development of chilblains, causes much suffering among persons who are obliged to carry on their work outdoors or in poorly heated places. In factories in which drastic measures are employed for the removal of dirt or stains, cleansing agents like chlorinated lime (chlorid of lime) or benzin used on the hands supplies the base for an eczema by divesting the skin of its natural secretions. Oil, which is used wherever machinery is installed, is the causative agent of acneiform and eczematous lesions in employees who operate or are otherwise engaged about such apparatus. In occupations which necessitate standing, persons who have a tendency to varicose veins not infrequently exhibit this condition with a secondary eczema and ulceration. Slight traumatisms lead to erosions of the skin which often become infected in patients who, owing to the venous congestion, have slight resistance. Young women who are obliged to stand at their work sometimes develop erythema induratum or Bazin's disease, which is characterized by nodules beneath the skin which may break down and produce ulcers. Some of these forms of Bazin's disease have been proved to be tuberculous. The infection is usually of benign type and readily yields to rest in bed, improved nutrition and a change to better hygienic surroundings (Fig. 1).

Many occupations bring about changes in the skin which are not pathologic in the strict sense of the word but are so characteristic for certain occupations that Blaschko has given these changes the name of "trade stigmata." These include localized thickenings of the horny layer in shoemakers, tailors, musicians, etc., bronzing of the skin in gardeners, farmers and other persons who follow outdoor occupations, staining of the hands of dyers, chimney sweeps, etc., pigmentation in workers in silver from a deposit of the metal and in millers from iron particles, etc.

The skin may respond to the most diverse irritants by the production of a catarrhal inflammation, or may develop different types of eruption from the action of the same agent. An example of the former may be found in the trade eczemas and of the latter in the effects of tar, which may cause eczema, acne, warty and epitheliomatous lesions, alone or intermingled.

The commonest type of occupation disease is an eczematoid dermatitis. In a recent article Herxheimer[1] enumerates seventy-four trades provocative of this form of disease. It may vary in grade and intensity from an erythematous and scaling dermatitis to a vesicular and bullous eruption. As the condition becomes chronic, infiltration of the skin takes place with desquamation and fissuring. With the cutaneous defenses lowered, pus infection is frequently superadded.

The excessive use of soap and water reduces the resistance of the skin by extracting the fat and macerating the horny cells. They may then act as direct excitants or prepare the way for some other irritant, as washing powders, etc. Severe eczemas of the hands and forearms are seen in those whose occupation requires them to have their hands continually in water, as in the case of washerwomen, housemaids, barkeepers, etc. In my clinic nearly one-third of the occupation diseases during the past year were seen in persons whose vocations necessitated the frequent employment of soap and water and, in some cases, the various cleansing alkalis.

In bakers a form of dermatitis of the hands and forearms is known as baker's itch. The exciting causes are the heat, the moist dough and saccharin solutions. A mite said to live in flour has also been incriminated. Candy-makers suffer from a similar eruption as well as from impetiginous lesions. Confectioners, bakers and preservers of fruit frequently show an eczema of the fingers and peri-ungual tissues from the action of fruit acids.

Winfield[2] describes a dermatitis in sugar-refiners which involves the hands, forearms and legs and resembles an impetiginous scabies It has been asserted that a mite found in raw sugar is responsible, but this lacks verification Oliver[3] says that in sugar factories a condition known as "lymphangitis of sugar-makers" is sometimes found among the sugar-refiners and molasses-stirrers It is accompanied by a slight constitutional disturbance, and a crop of boils is not an unusual sequel *According to Gaillot the lymphangitis is an infection* caused by the *Staphylococcus pyogenes aureus* This organism is said to be found not in the freshly made molasses but in the residue, the temperature of the factory and the condition of the skin of the workers favor its development

[2] Personal communication.

Builders and masons develop an eczematous affection of the exposed parts of the body from the irritating effects of lime and cement In stone-cutters an analogous condition is caused by the stone dust A palmar dermatitis is also seen in brickmakers

Metal workers, from the constant irritation of the dust or filings, or from the direct cauterant action of these or the acids or turpentine used in the various processes, suffer from all grades of inflammation to intractable ulceration

Printers and machinists, from contact with chemicals and oil, often develop a chronic eczema of hands and forearms Electroplaters are also liable to an inflammation of the hands and forearms from the use of a mixture of lime dust and olive oil in "finishing," and from sour beer in the process known as "scratch brushing"

Workers who handle the chromates in the arts and trades suffer from an eczematous eruption as well as from ulceration of the skin and mucous membrane which shows little tendency to heal

Hydrofluoric acid, employed in the manufacture of glass, the bleaching of cane, washing of manure, etc, produces sores of the nasal orifice and gums and painful blisters and ulcers of the skin

The irritant action of arsenic on the skin is well known In the arts and manufactures in which its compounds are employed workers are attacked with eczema or ulcerative or gangrenous lesions, which may be present on the face, neck and extremities, but more especially on the genitals In color-works, ulcers of the hands are designated "arsenic pock" Arsenic sulphid which, with lime, is used in curing fur, sets up a very severe dermatitis in furriers, not infrequently with persistent ulceration (Fig 2)

Chemists are prone to inflammation of the hands and sometimes of the face from handling various drugs and chemicals Their skin often develops so marked a susceptibility that minute quantities or even fumes will call forth an outbreak I have several times noted a similar anaphylactic condition from formaldehyd solution in laboratory workers Another familiar example of an eczema caused by chemical action is eczema of the hands of physicians and nurses from the use of antiseptics, notably mercuric chlorid and phenol (carbolic acid) These forms of dermatitis are very rebellious to treatment

Among miners, smelters and photographers an eruption of erythematous and pustular type is sometimes encountered from the irritant effects of mercury Photographers are also subject to an eczema more especially of the terminal phalanges and nails, from other reducing agents, particularly pyrogallic acid In hat factories eczema of the hands is said to result from the manipulation of hot water acidulated with sulphuric acid

The eczema in tobacco-workers is believed to be caused by the caustic solutions used in separating the tobacco leaves

Calico-printers suffer from eczema fissures and wounds which often become infected The cause is attributed to the bleaching and cauterizing substances handled

In flax-workers and linen-workers various skin affections are reported, among them a follicular eruption caused by the oils and irritating materials used in this occupation In Belgium many of the flax-workers show a peculiar abrasion and ulceration of the palmar surface of the hands Fissures form, exfoliation takes place and when the deeper structures are involved the condition simulates a syphilitic lesion An eruption resembling small-pox has also been described on the forearm, arm and face of workers who remove the bobbins from the spinning-frames From the pressure and friction caused by pulling threads the persons who engage in this part of the work present callosities on their index-fingers

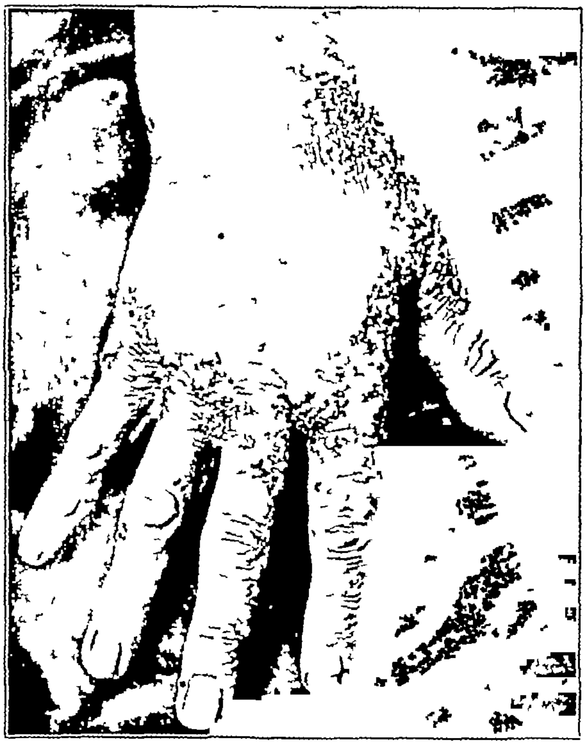

Fig 2 —Chronic eczema of the hand in a furrier

Callosities of the palms are also seen in laborers, engine-runners, etc Among miners they form a special dermatosis called "beat hand" Painful thickenings develop over the regions where the handle of the pick makes greatest pressure, along the bases of the fingers, and over the ball of the thumb and outer side of the hand The subjacent tissue becomes inflamed and not infrequently is further complicated by suppuration To this condition the term "keens" is applied

Warts sometimes form troublesome lesions on the palms of persons engaged in manual work In some cases they are purely epidermic growths, in others in which the epidermis has been removed, the underlying tissue as the result of irritation becomes the seat of exuberant granulations with papillomatous formation

Dyers and workers in anilin colors are apt to develop eczematoid and pustular eruptions on different portions of the body The bad effects are not limited to those in this trade, but the wearers of clothing prepared with certain of the dyes may ultimately be the victims of a severe dermatitis. The black, red and orange-yellow pigments are particularly irritating, marked inflammatory reactions having been caused by socks, gloves, underwear and shoes so colored. I have also seen unusually severe forms of eczematoid dermatitis in barbers who had employed proprietary anilin hair-dyes on their patrons (Fig 3). It is not an uncommon experience in dermatologic practice to be consulted for a dermatitis of the face, neck and ears which had followed the application of some of these hair-dyes. In susceptible subjects the use of hair-tonics may produce similar trouble. Another dermatologic condition common in anilin workers is hyperhidrosis of the palms caused by washing the hands with chlorinated lime for the removal of the dyes. According to Blaschko,[4] it may be so intense as to amount to a flux. The affection is also seen among employees in chlorinated lime and soda works.

---

[3] Oliver Thomas Diseases of Occupation E P Dutton & Co 1908

The manufacture of calcium chlorid and sodium and potassium chlorid by electrolysis is sometimes attended by an erythematous and edematous inflammation of the face of the workmen, resembling erysipelas. This is attributed to the sodium hypochlorite that is formed. With the subsidence of the acute process an acneiform eruption is left behind, the so-called chloracne. This is the commoner cutaneous malady seen in this occupation and is characterized by the early development of blackheads on the face, trunk and extremities followed by a grayish discoloration of the face. Inflammation and suppuration of the follicular glands is not uncommonly followed by nodules, pustules, boils and disfiguring scars.

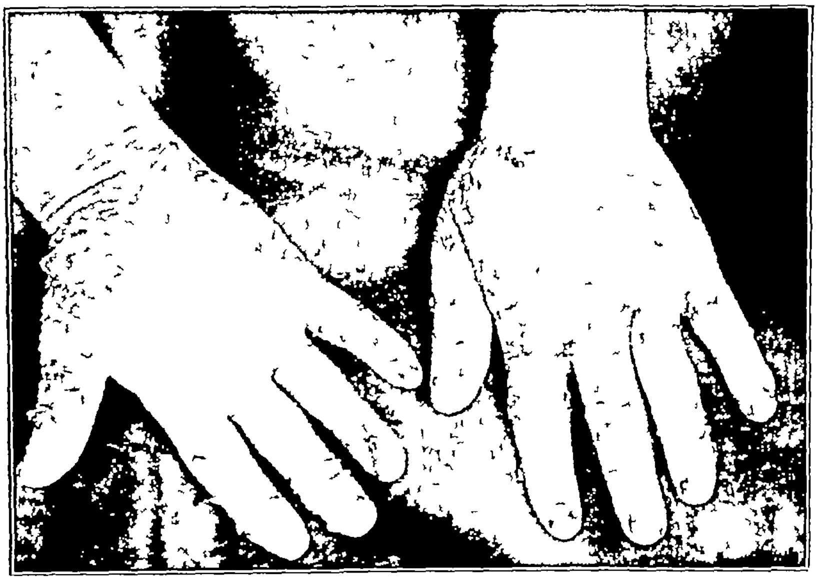

Fig 3.—A dermatitis of the hands in a barber resulting from the use of hair tonics employed on his patrons.

Tar-workers and paraffin-workers develop a similar eruption which may last several months and then change to the so-called "tar itch." This is accompanied by hyperkeratosis and increased activity of the sebaceous glands, forming plaques and crusts, with the further development of multiple warts, one or more of which degenerate into malignant growths. The disease affects chiefly the hands, forearms and scrotum. It progresses slowly and in many instances no recurrence takes place after removal of the epithelioma. Oliver cites the case of a man aged 58, who had worked among coal-oil and tar products for thirty-years. He presented numerous indurated patches, some of which had ulcerated, as well as multiple black warts and scars, the remains of old ulcers. His son, aged 27, following the same employment, developed a malignant growth of the forearm which necessitated amputation. Metastases of the axillary and cervical lymph-nodes took place and the patient succumbed to secondary carcinosis.

Cancer in chimney-sweeps has been reported chiefly from England. The soot produces a chronic irritation of the skin and when retained in such regions as the folds of the scrotum causes warty growths which become epitheliomatous. In some instances the hands, arms and thighs have been involved. With the advent of machinery for cleaning chimneys the incidence of scrotal cancer has been markedly reduced. It is reported that gardeners who employ soot for the protection of plants from slugs in a like manner show the effects of this irritant in the development of malignant growths of the hands.

Gardeners and florists frequently suffer from some form of inflammation of the hands and arms occasioned by contact with certain plants. It is estimated that between sixty and seventy plants possess this irritant action and the power to induce a dermatitis. The more familiar ones are poison ivy, poison sumac, primrose, chrysanthemum and eucalyptus, the eruption varying from a simple erythema to marked swelling with the formation of vesicles and bullæ. Not only are the exposed parts involved but the affection may be carried by the hands or clothing to other portions of the body. It is probable as in the case of *Rhus toxicodendron,* that the active principle in the majority of these plants is an essential oil. Lacquer,[5] which is obtained from a tree belonging to the genus *Rhus,* produces a dermatitis either by direct contact or through the fumes by evaporation. The symptoms, consisting of fever and edema of the skin of the face, limbs and generative organs, nasal and conjunctival catarrh, and a papular eruption of the legs and forearms, appear in a few hours.

The resinous dust of certain hard woods, like teak, ebony, satinwood, rosewood and others, will occasionally set up a dermatitis in carpenters and joiners. In teak, the exciting agent is believed to be an essential oil derived from the central part of the tree and present in the dust. The symptoms are sometimes very severe, the eruption becoming generalized and accompanied by vomiting. It may last for several months and is quite apt to recur when the patient resumes work.

The so-called polisher's itch of the forearms and hands, found in furniture-polishers, is attributed to the methyl or impure alcohol present in varnishes and polishes. Impure turpentine and benzin used for cleansing purposes likewise provoke an eczema of the hands.

In persons who follow an outdoor occupation the uncovered portions of the skin sometimes undergo peculiar degenerative changes. Under the name of

---

[5] Castellani and Chambers Lacquer Poisoning, Manual of Tropical Medicine 1910 p 118

"sailor's skin," Unna has described an affection which he observed chiefly in seafaring men A diffuse cyanotic redness, not unlike chilblain, develops at first on the ears, adjacent parts of the cheeks and temples, the backs of the hands and fingers The skin then becomes mottled, pigmented, rough and hard and in places papillomatous These warts may last for years and slowly undergo a malignant change A similar condition is seen on the face, neck and hands of people who follow agricultural pursuits The cause is sought in the actinic rays The effect of light on the skin is illustrated in *x*-ray workers, in whom, unless protected, the hands become the seat of a mild erythematous squamous eruption, more or less persistent, which is succeeded by pigmentation, telangiectases and atrophic wrinkling This condition may remain unchanged or keratoses may be added which develop into epitheliomas

Drivers and coachmen exposed to the rigors of the weather are often the subjects of the severer forms of rosacea The use of alcohol, however, to which many of these people are addicted, cannot be wholly ignored as a contributing etiologic factor

Certain callings, notably those dealing with dead or live animals or their products, favor the development of infectious diseases Owing to the prevalence of pyogenic organisms, local pus infections, as boils, carbuncles, impetigo contagiosa or cellulitis are not infrequently encountered in butchers, slaughter-house men and other individuals who handle dead animal matter A generalized bullous dermatitis with severe constitutional symptoms and a high mortality has also been observed The starting point is usually an infected wound Several years ago Bowen[6] pointed to a possible relationship between these cases of so-called acute infectious pemphigus and foot-and-mouth disease of cattle, as he had observed such instances during an epizootic of the latter disease in New England Foot-and-mouth disease takes place by inoculation of the skin or mucous membrane in butchers, dairymen, stable boys and drivers Herxheimer records having seen a case in a horse dealer

The parasitic diseases which are more definitely identified with particular avocations are tuberculosis, anthrax, glanders and actinomycosis

Inoculation tuberculosis occurs in its simplest form as verruca necrogenica, or anatomic tubercle It is encountered chiefly among medical students, physicians, hospital ward attendants, and butchers as a localized papillomatous formation usually about the knuckles or other parts of the hand or forearm

Anthrax is uncommon in this country, but it is prevalent in animals in certain parts of Europe and Asia, especially cattle and sheep In man the disease occurs as the result of direct infection from such animals or their products via the skin, the intestines or more rarely the lungs It is seen in the wool-sorting, wool-combing and spinning industries, horse-hair and brush factories, in stevedores, wharf-laborers, carters, farmers, shepherds, butchers meat inspectors and cattle salesmen The internal form is known as wool-sorter's disease Of the external, which is also the more usual, there are two varieties, the malignant pustule and malignant anthrax edema, which is the more fatal of the two

Glanders, usually contracted from horses, is seen almost exclusively in hostlers or those who have to do with these animals It is rare in this country The bacillus may gain entrance through the mucous membrane of the eye, nose, mouth or respiratory tract, or the site of inoculation may be a lesion of the skin Clinically the disease is divided into glanders and farcy, according to whether the lesions of the mucous membrane or skin predominate Both types present an acute and a chronic form

Actinomycosis is endemic in cattle and more rarely affects horses, hogs and other animals In man the disease is seen in those who come in contact with such animals or handle fodder or grain, as farmers, coachmen, dairymen, millers, etc Infection in man takes place through a carious tooth or lesion in the mouth and less often through the skin The ray fungus is believed to flourish on corn, hay and cereal grains, as the latter have frequently formed the nucleus of an actinomycotic lesion

Erysipeloid, an infection of the skin caused by poisoning from meats, fish, poultry, cheese and similar animal products, is seen chiefly in butchers, fishmongers, poultry-dealers, cooks, and scullions Gilchrist[7] observes that crab bites and injury by crabs are a frequent cause The disease is believed by Rosenbach to be caused by a microorganism of the order *Cladothrix* It is characterizeed by one or more areas of slowly spreading inflammation, clearing up at the part originally affected and progressing slowly to new areas, the advancing border being festooned or scalloped Burning, pricking or itching sensations accompany the affection, which involves chiefly the fingers and hands

Among the minor infections may be mentioned ringworm transmitted from horses dogs and other domestic animals to men and boys employed about stables or engaged in the care of such diseased animals Ringworm of equine origin is characterized by the formation of irregular and projecting nodular lesions studded with pustules involving the beard region, neck, wrist or hands

In certain grain regions infested by a mite, *Pediculoides ventricosus,* an intensely itching urticarious eruption is endemic among the farmers and laborers who handle sacks of wheat, barley and other grains or straw harboring this parasite Small epidemics have also appeared at different times from the use of mattresses made from straw which the organism has made its habitat To Dr Jay F Schamberg[8] belongs the credit of priority in describing the affection in this country

In conclusion, while many of the industrial dermatoses lead to little inconvenience, some forms of dermatitis may become so severe that they absolutely prevent a man from carrying on his occupation In certain susceptible individuals the action of the irritant is confined not only to the parts exposed but may spread over the entire body Patients who develop such an idiosyncrasy should be guarded against these forms of dermatitis becoming permanent and advised to use the best means of prevention Such measures cannot be discussed at length in a paper of this scope as they must necessarily fit individual cases If the nature of the work permits, the wearing of masks and gloves to protect the exposed parts, as practiced by Chinese lacquerers, is advisable, but obviously this is not feasible in all forms of occupation The use of soap and water is to be recommended in some trades in order to remove the noxious substances, while in those instances in which they prove to be the irritants they are positively injurious and should be sparingly used In any case, after washing, the hands should always be carefully dried and if practicable covered with a protective ointment, or a salve or cold cream should be thoroughly rubbed into the skin at night Persons whose vocations bring them in contact with live or dead animals or their products should be instructed as to the mode of inoculation of infections from these sources, and all wounds or breaks in the continuity of the skin should be sealed with collodion, plaster or other protective dressing

OCCUPATIONAL EYE DISEASES AND ACCIDENTS *

MARK D STEVENSON, M D
Member of the Committee on Prevention of Blindness of the American Medical Association
AKRON, OHIO

A complete catalogue of the various trades and industries in which accidents, even preventable accidents, causing partial or complete blindness of one or both eyes, although suggestive, would be of little service and would necessarily include nearly all the causes of accidents in general It will not be without profit, however, to consider those industrial accidents which are of frequent occurrence Space forbids full consideration of the effects on the eyes of environment, lighting, improper or excessive use of the eyes, the special toxic effect of alcohol and tobacco, and special infections in the ordinary occupations

COMMON, PREVENTABLE ACCIDENTS

I shall first discuss common accidents to the eye in foundries, machine-shops, mills, and in the building trades, domestic, agricultural and military pursuits, which can be greatly lessened by various known means, such as have been applied among iron workers, mechanics or weavers

These accidents include blows from blunt force and wounds of all description — incised, punched, lacerated and contused—occurring from the use of tools or caused by foreign bodies of all kinds, magnetic or non-magnetic, retained or not within the eye Ordinary domestic injuries, in addition to the above, include scratches of the conjunctiva or cornea and wounds from knives, scissors, forks, useless air-guns, fireworks, improperly carried umbrellas, etc

Blows from blunt objects on the eye or its surroundings may cause ecchymosis and swelling of the lids, fracture of the orbit, ecchymosis and hematoma of the conjunctiva or orbit, rupture, concussion or dislocation of the eyeball, rupture or paralysis of the muscles, rupture of or pressure on the optic nerve by hematomas, aneurysms or fractured bones In addition the iris may be torn, the lens dislocated and the various structures within the eye injured The base of the skull may be fractured and traumatic exophthalmos result

Small particles are likely to become lodged in the cornea of workmen of various trades, especially in the iron and steel trades This is common in the eyes of grinders, especially dry grinders who do not use a wet stone, small particles of the metal being ground off the stone or emery-wheel used Close examination, with a magnifying glass or loupe, of such workmen's corneas, often peculiarly insensitive, will usually show large numbers of minute scars, sometimes so numerous as to dull the cornea and affect the vision Fans making air-currents so as to pull or blow the particles away from the eyes are important in many trades, the fans also prevent the inhalation of foreign particles or noxious gases, thus securing better ventilation and benefiting the general health Various shield devices, solid and adjustable, are now on the market They are used generally by the United States Steel Company and are exhibited in the American Museum of Safety in New York of which Dr Tolman is in charge These shields are placed on grinding-wheels, circular saws, lathes and many forms of rapidly revolving machinery, helping to prevent particles flying against the workman's face, and are a safeguard against accidents in case the revolving parts should break Recently much has been done to prevent revolving wheels, etc, from breaking by the use of proper compressible washers, larger than the flanges, making proper application and distribution of pressure to a large space on the side of the straight-sided wheels The flanges are more than half the diameter of the wheel and bear only at their circumference on a flat surface The caliper-rest is adjusted as close to the wheel as possible, lessening the danger of the material being caught between the wheel and the rest Large protecting glasses or the worker's own lenses, if he wears any, are also of much service in preventing particles getting into the eyes, as well as for saving the eyes from more dangerous accidents from large flying particles Glass protectors are also made surrounded by wire gauze as in goggles Unfortunately they get dirty and marked with the frequent blows from flying particles, so that the workmen, unwilling to accept such pressing testimony of their use, too often lay them aside

Injuries from these small flying particles may be slight or serious. Sometimes small particles puncture the coats of the eyeball and unless removed, especially if metal, endanger both eyes by causing sympathetic inflammation, which according to Magnus is the cause of from 4 to 4 5 per cent of total blindness In some cases infection results, giving rise to dangerous ulcers which sometimes destroy partially or wholly the eyesight or even the eyeball Serious accidents to other parts of a workman or even to other workmen sometimes occur, because an operator with a foreign body in his eye cannot see sufficiently to manage machinery The opportunities for slight or severe eye injuries in iron and steel workers are multitudinous and occur in all branches of the work, light or heavy

Many of these accidents occur in chipping, fettling or dressing rough edges of castings, ingots and even large armor-plates These chippings are brittle and sharp and fly about, often bounding from objects which they strike The accidents are caused by one or two strikers hitting a chisel held against the casting by another man Particles are likely to fly not only from the metal struck but also from either end of the chisel or from the hammers of the strikers S C Ayers has pointed out that cheap hammers and chisels of poor quality are frequent causes of eye accidents in mechanics Care is taken in some shops to examine carefully and regularly these tools to prevent accidents Pneumatic chippers are safer Passersby and other workers may be protected by chipping against a wall or a screen covered with canvas or burlap which will hold the flying particles and not reflect them Brick-cleaners should take similar precautions

Burning sparks and flashes are commonly caused from molten metal running into molds, in great or small

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association at the Sixty Third Annual Session held at Atlantic City *June 1912*

forgings, by hand steam or hydraulic hammers When there is great heat, glass protectors to the eyes are of little service, but good safe protectors of wire gauze covering both eyes and face, especially those with asbestos over mouth and neck, are useful Rusting may be provided against by making the frames of galvanized iron or aluminum wire

Coal-miners are likely to be injured by small particles of coal or splinters from the pick point becoming embedded in the cornea, abrading its surface or cutting it Such wounds are particularly likely to become septic Agriculturists often meet with eye accidents in threshing, chaff-cutting, hedging, in distributing artificial fertilizers and by the entrance into the eye of spears of grains and grasses, twigs and leaves, and from insects and their stings These injuries are usually produced by vegetable substances, straw, beards of wheat, etc, and are likely to become infected Cow-horns, claws and kicks from animals cause many accidents In taking care of some plants special forms of affection result, as ophthalmia among hop-pickers due to entrance of fine, thin hair-like processes from the hop leaves Dusty labor is liable to cause troublesome eye conditions as in sawmills from flying sawdust and knots, at threshings, in handling coal and ashes, in flour-mills and from fine particles of copper off trolley wires, but the eyes can be greatly protected by proper goggles

Stone-masons, grindstone-makers, quarrymen, bricklayers and stone-breakers can partially protect their own eyes by proper protectors and should be more careful to dress their work against some wall where passersby will not be so likely to be injured Wire-drawing, in which great tension is placed on the wire, causes accidents from breaking or slipping of the wire which backlashes and may strike some one In weaving there is great danger of a flying shuttle striking the eye, but many patterns of guards are now on the market to prevent this Some are known as wing guards, consisting of a wire screen or canvas placed between the looms, others provide means to prevent the shuttle from rising The military man and sportsman are subjected to the danger of small and large shot and bullets, shell explosions, sword and bayonet injuries and explosions of various kinds

There are various processes involving exposure to irritating dusts, as to the dust of graphite in the manufacture of stove polish, bronze powder, while bronzing in lithographing, in all processes of grinding, glazing or polishing, and while talc (soapstone) dusting in rubber manufacturing In sorting, dusting, cutting or grinding rags, and in cutting, boring, turning, planing, facing, doming, grinding or polishing pearls or buttons, shell dust is also likely to get into the eyes Everywhere in the air volcanic and meteoric dust is present, the latter consisting of tiny spherical shot-like pellets from 1/200 to 1/500 of an inch in diameter The flinty shells of diatoms, tiny plants, and dust from sandstones and deserts often get into the eyes The pollen of plants as from pine-trees, scales from the wings of butterflies and other insects, and hairs as from caterpillars, also get into the eyes

ACCIDENTS FROM EXPLOSIVES

Accidents occur while high explosives are being handled, as in clay manufacturing quarrying, mining and railroad construction

Blasting in mining, quarrying etc, causes a large number of accidental injuries These accidents are particularly liable to destroy both eyes, removing the earning capacity of the individual and possibly throwing him on the community for support Powder-grains are often embedded in the eyeballs, lids or face Most high explosives, unlike gunpowder, are not exploded by simple ignition but require an exploder Poor fuse or explosives, possibly frozen, with improper loading cause premature blasts or misfires Accidents usually occur from drilling these "missed holes," striking an unexploded piece of explosive, cap packing with a metal instead of a wooden tamping rod, carelessness with cigar ashes, hot candle grease or in handling the explosives Donovan[1] states that blasting injuries with few exceptions result from want of care on the part of the patient, his associates or his predecessors at work Large quantities of explosives, whether solids, liquids or gases, should not be stored in any one place, especially in thickly settled communities Greater care in proper insulation of electric wiring in such regions and the prevention of the possibility of sparks by short-circuiting should be observed Licensing of "powder men" and better government inspection of the manufacture, storage and sale of explosives would be helpful

ACCIDENTS FROM FLYING GLASS

Accidents to the eyes occur from the bursting of locomotive oil- and water-gauges, and bottles and siphons in bottling

Gauges on every description of steam boiler frequently break, injuring by flying pieces of glass, or scalding by the steam or hot water The slowly soluble gauges are worn by the friction of the moving fluids within and may be protected with wire netting or plate-glass protectors open at the back, so that the direction of an explosion may be controlled The chief danger comes when putting in a new glass after one is broken On turning the hot water into the cool glass it suddenly breaks The United States Steel Company has swinging wire protectors that may be placed in front of these gauges until the glass has been warmed and tried, when the protector is swung out of the way so that it can be more readily seen by the engineer at a distance These accidents, occurring to engineers, who require a high degree of visual acuity, greatly lessen their earning capacity and at the time of the accident may endanger many lives and much valuable property

In the manufacture of aerated waters and in bottling beverages of nearly all kinds, the frequent bursting of bottles and siphons is very dangerous to the eyes The bottles are cleaned, filled, corked and wired by machinery and in all the various processes and inspections which are necessary, there is danger of the bottles bursting The Dangerous Trades Committee of Great Britain, in 1896, recommended that all bottlers, wirers, sighters and laborers while at work should be provided with face-guards, masks or veils of wire gauze They also recommended the providing of gauntlets for the arms and the fencing with wire gauze of all machines for bottling, to prevent fragments of bursting bottles striking any workers

ACCIDENTS FROM SCALDS AND FUMES

Accidents somewhat similar to the preceding are caused by scalds or caustics or exposure to irritating gases and fumes as from hot fluids, molten metals, lime or corrosive acids or alkalies entering the eye sac

Scalds or burns usually involve the eyelids, the deeper burns affecting the eye generally result from explosives as in preventable Fourth of July accidents Powder-burns should be treated with hydrogen peroxid,

[1] D The Journal A M A Aug 5 1905 p 387

and Wurdemann then applies for from six to twelve hours 33⅓ per cent papain in glycerin to digest the injured tissue, afterward applying 5 per cent boric or other simple ointment Powder-grains or other foreign bodies in the cornea require the use of a local anesthetic and spud Burns in masons, plasterers and bricklayers caused by lime, especially unslaked lime, calcium oxid, sometimes result in destruction of the cornea and frequently in traumatic pterygia and adhesions between the eyelids and globe and, because of chemical combination with substances in the cornea, produce permanent opacities When unslaked lime gets into the eye it should be wiped out by a dry clean cloth or washed out with liquid petrolatum or castor or olive oil If this is not done at once the lime will soon be slaked by the tears and then large quantities of water can be used to help remove it Besides causing actual destruction, lime and cement have irritating qualities, sometimes occasioning conjunctivitis and even ulceration of the cornea with loss of vision in those who work constantly with these substances There are also various caustics employed, as in the manufacture of chemicals, alkalies and acids

Proper, clearly worded signs, giving warning of the dangers from careless handling of caustics in shops and schools, would lead to greater care being exercised In accidents caused by unslaked lime and certain corrosive fumes, workmen should pour olive or even castor oil (quantities of which should be kept handy in certain trades) into the eye If oil is not quickly obtainable large quantities of water should be used There are certain advantages in the use of water in that the inexperienced find it very difficult to manipulate the slippery lids after the first drop of oil has been used

Ammonia burns should be treated immediately by *profuse irrigations with water, according to* Pichler[2] For workmen compelled to use certain acids or alkalies proper neutralizing washes should be supplied so that fellow-workmen, properly instructed may use them at once After burns of the cornea by acids, Guillery[3] advises bathing the eyes with 0 5 per cent solution of potassium hydrate, and says that the opacities from lime may be partially cleared by the use of a 10 per cent solution of ammonium chlorate with 0 1 per cent tartaric acid For lime-burns Wurdemann advises copious washings with cold water and the use of from 3 to 10 per cent solution of ammonium chlorid, the calcium being dissolved and carried away Any mildly acid solution may be used for recent burns with alkalies Schmidt[4] asserts that corneal burns from acids are likely to cause opacities of the lens Exposure to irritating gases and fumes takes place chiefly in gassing in textile factories, singeing in print works, bleaching and dyeing works and in dipping metals in acid solutions

DISEASES FROM INTENSE LIGHT AND HEAT

Diseases resulting from excessive light or heat are not uncommon among electric welders, steel smelters and in those melting or annealing glass

Metal-polishers and buffers, brightening surfaces which they must closely watch, often suffer with hyperesthesia of the retina This can be relieved by proper lenses or colored glasses Excessive heat and light are encountered in iron and steel works Men can watch a *furnace* until the temperature reaches 2,000 F, but before it rises to 3,000 F, colored glasses should be worn In working with cast iron, from 1,800 to 2,000 F, the men take few precautions, with molten metal, 2,700 to 2,800 F, deep blue glasses are necessary With Bessemer metal, 3,000 to 3,200 F, the process is completed in about twenty minutes and only one man needs to watch the metal, which he does with a spectroscope about 30 feet distant The Siemons process takes ten hours and all the men, wearing colored lenses, make observations frequently If some of these hot furnaces are looked into without lenses it is several minutes before the eye can see ordinary objects again Some men seem to have surprising immunity from bad results in dealing with these white-hot furnaces, others cannot endure them and must change their work Snell doubts the greater frequency of cataract in glass-blowers and iron-workers than in others, although both are subjected to great heat and consequent loss of moisture Herbert Parsons and Marcus Gunn in 1908 visited some of the important glass-works in England to gather statistics of industrial diseases for the framing of the workmen's compensation act They state that bottle-makers have a characteristic form of cataract, typically, a dense, well-defined disk of opacity in the center of the posterior cortex Often slight opacities surround this posterior cortical disk Excessive heat and bright light are said to be the causes but the Germans claim that heat is the most important cause Weyl mentions, besides glass-blowers fire workers, puddlers, blacksmiths, bakers and cooks

Great care is required to avoid very strong light flashes before the eyes, as in short circuits and electric welding In the latter large shields are worn, in the center of which are four alternate layers of blue and red glass Helmets and screens with four or six layers of red and green glass are often used The temperature in electric welding goes as high as 7,000 F, but the question of whether it is the heat or the chemical rays that act so harmfully has not been settled If the eyes catch the light they are affected at once, but chiefly some hours afterward They feel swollen as if filled with burning sand and the pain is usually very severe, the lids are swollen and there is much lacrimation Intense light as from electric and vapor lamps, from exposure to snow or after observing an eclipse, frequently causes a superficial ophthalmia and may affect the lens and retina

Schanz and Stockhausen found that the superficial irritation could be prevented by a screen of euphos glass which absorbs ultraviolet rays McMullen[5] states that this could be done with plain glass which absorbs rays of wave-length less than 300 microns He thinks that opacities in the lens result when the wave-lengths are between 300 or 400 microns, but that the rays of greater length, as well as the short waves, cause the retinal changes Wurdemann says that electric light flashes or lightning may cause cataract and by being focused on the macula destroy the central retinal elements

DISEASES CAUSED BY POISONOUS SUBSTANCES

Diseases result from working in certain poisonous gases and fumes, dusts or substances, bisulphids of carbon, lead, etc

Dinitrobenzol is largely employed in making explosives During the various processes of its manufacture fumes are given off which affect vision These can be lessened by properly covering the mixtures and by the use of fans and exhaust apparatus Respirators and glasses are used The general circulatory and nervous effects are described by Snell,[6] who gives many excellent suggestions for preventing deleterious effects in manufacturing this substance Carbon bisulphid, formerly much used in vulcanizing rubber, caused impaired eyesight, but this process has been so greatly modified that it is now of little importance in causing ocular lesions Toxic amblyopias caused by tobacco, ethyl alcohol and wood alcohol are too well known to require consideration

The eye affections formerly attending the manufacture of iodoform have by care been eliminated A few cases of eye involvement have been reported in dye factories from handling the various coal-tar preparations Arsenic from wall-paper, artificial flowers and Paris green, paper hangings and paintings, also when used for medical or cosmetic purposes, according to Casey Wood, has caused various visual disturbances Painters, plumbers, electrotypers, file-cutters and many others through handling lead are likely to get chronic lead-poisoning causing central peripheral affections of sight, various paralyses, retrobulbar neuritis, etc Lead-poisoning is also found among those manufacturing white, yellow, orange and red lead, lead pipe, solder and plumbers' supplies and in cutting metal articles composed of lead or lead and tin, in grinding lead paint, making storage batteries, cleaning or handling printing type and in glazing in pottery establishments Poisonous gases and fumes are found in shoe cement, japanned or patent leather and rubber manufacturing, in which the mixtures containing naphtha are sometimes allowed to remain in uncovered containers and proper ventilation is not insisted on Poisonous gases are also formed in certain lead processes

DISEASES DUE TO PECULIAR OR PROLONGED USE OF THE EYE

Nystagmus in miners is an instance of the diseases found in workers following occupations requiring prolonged and peculiar use of the eyes

Nystagmus in miners, due to their peculiar way of looking at their work, is fully described by Snell, who says that treatment consists in changing the kind of work After relief the miner can return to his work if the head can be kept straight and the eyes are not often turned upward Snell mentions several other occupations which he has thought might cause nystagmus because the eyes were turned directly or obliquely upward

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS STEVENSON AND FORDYCE

DR CHARLES F STOKES, Surgeon General, U S Navy, Washington, D C Our activities in the Navy along the line of occupational hygiene are undertaken entirely to add to military efficiency, our humanitarian interest being subordinated and secondary General sanitation has reached a very satisfactory plane We have, however, grouped together in a battle ship a more varied lot of activities, I think, than will be found elsewhere in the same space There are disabilities attributable to the use of the searchlight, which is illuminated by an arc light, inducing a coagulation in the retinal cells or changes in optic nerves We aim to avert these disabilities by the use of electrician's glass to cut down the intensity of the light, and the use of Hallauer glass to diminish the deleterious effect of the actinic rays In the turrets the gun pointer adjusts or refines the pointing of his gun by means of a telescopic sight We are studying the effects of these telescopic sights on the eyes, and are taking steps to avert disability from this cause There is a menace in the double bottoms of battle ships which has to be taken into account I know of an instance in which two men lost their lives while inspecting double bottoms in a foreign navy A study of the conditions there has led us to believe that they are not due to toxic gases, but rather to a diminished amount of oxygen During battle practice we find that there are conditions in turrets which will have to be remedied otherwise our men will not be so effective as they should be We find that humidity runs rapidly up to saturation that the normal carbon dioxid content of the air runs up to a dangerous point, and we find as well powder gas contaminations in these situations Steps are being taken to avoid these conditions Our activities in some of these situations have gone so far that they are looked on as a great military asset, and as such are to be regarded as military secrets We have been studying the atmospheric conditions in submarines with the hope of being able to sustain life beyond the time it is now possible to do so in the case of disabled submarines The problem here is not so simple as it would appear at first thought It is something more than the generation of oxygen It means the destruction of carbon dioxid, the taking up of humidity and the doing away with battery generations, principally hydrogen and sulphuric acid, and carbon monoxid from back firing of gasoline We have been making systematic and careful observations in the fire rooms of our battle ships, studying the personnel and the chemical atmospheric conditions before, during and after endurance runs We believe that some of the cases of heat exhaustion, or heat prostration, are due to some extent to a gaseous contamination, possibly carbon monoxid

DR WALTON FOREST DUTTON, Carnegie, Pa An occupational disease not very well known is vanadiumism There are only about two reduction plants in the United States, and in those plants the frequency of the disease has run very high The disease will become more prevalent as vanadium products become more generally used They are being used more and more every day, especially in the manufacture of steel in photography and in cloth manufacturing plants where mordants are used The pentoxid is used in photography quite a great deal Vanadium chlorid and peroxid are used as mordants in printing fabrics, the peroxid is used in the manufacture of steel The greatest number of cases of vanadiumism are found in the reduction plants, especially in the men on the mixing floor and in those that work about the crucibles This disease is not well known at the present time, but it will become more familiar to physicians as the use of vanadium products increases An article that appeared in THE JOURNAL, June 3, 1911, p 1648, will probably give a better description of the poison

SOME TYPES OF URETERAL OBSTRUCTION IN WOMEN *

HENRY DAWSON FURNISS, M D

Assistant Attending Gynecologist to New York Post Graduate Hospital

NEW YORK

The type of ureteral obstruction considered in this paper is that due to lesions in the ureter itself, and while tuberculous conditions fall in this category, they are, for the sake of brevity, omitted

The interest for such a study was furnished by the discovery of a number of cases, most of which had been unrecognized and treated for other conditions I feel confident that I have overlooked a number of these for they presented the same symptoms as those in which I have determined beyond doubt the presence of ureteral obstruction The [illegible]very of the first case was more or less [illegible] it so imp[illegible] I have been [illegible] and have [illegible]igh others to make me think it a frequent condition in women

In reviewing the reported cases I find that most of them give histories of long-standing trouble, and marked kidney and ureteral changes above the obstruction In other words, they had remained unrecognized and untreated until urgent symptoms demanded operation In a large number of the patients operated on, the operation was exploratory, for no definite diagnosis had been made

In explanation of the etiology of this condition, congenital malformation is given as the most frequent cause Bottomley,[1] who reviews the literature and abstracts the cases reported to date, regards the condition as congenital, but some of the histories read much as if the obstruction were acquired and of inflammatory origin J Verhoogen and A deGraeuwe[2] are of the opinion that most of these strictures are due to congenital defects that become symptom-producing on the addition of a secondary cause, and that infection is the chief one The number of cases seen in the individuals possessing no other apparent congenital defect leads one to suppose that too much blame has been placed on congenital abnormalities, and that some other cause, or causes, must be at fault

In a study of the histories of my cases I am led to assume that infection plays the important part in the production of ureteral stricture Acute hematogenous infections of the kidneys from infections arising from wounds, furuncles, in the course of infectious diseases, especially influenza, tonsillitis† and typhoid, intestinal disturbances and operations on the intestinal canal, etc, are rather frequent They often persist as a pyelitis, ureteritis or a secondary cystitis The long-continued inflammation then results in an infiltration of the ureter with consequent contraction and the formation of a stricture This represents obstructions from infections of the descending type Sugimura[3] studied the lower end of the ureters in the bodies of twenty-five patients who had had cystitis but died of other causes, and in all found changes of an inflammatory type in the submucosa and muscularis, he expressed the opinion that the infection extended through the lymphatics and not along the mucosa

Of the infecting organisms the colon bacillus has been given first place, and most authorities consider that in this type the infection descends from the kidney Just how important a rôle is played by the gonococcus is still in dispute but when this is the causative factor the path is generally ascending Garceau[4] believes it more frequently to blame than does Kelly and suspects it strongly in cases of bilateral ureteritis or stricture

The seats of stricture are, as a rule at the points of anatomic narrowing, with the ones at the vesical end and just below the pelvis as the most frequent, stricture at the point of crossing of the pelvic brim being rare Kelly[5] claims to have seen only once stricture of the upper end, but this does not agree with my experience or with the literature John A Sampson[6] reports a case of stricture of the lower end of the ureter with a valve-like formation at the pelvic brim that he explains as being due to the giving way of the ureteral sheath at that point with a hernial protrusion of the ureter I have radiographs of two cases that show much the same picture as that in the diagram illustrating his case

Necker[7] exhibited before the Deutsche Gesellschaft fur Urologie at the congress in Vienna in September, 1911 some pyelograms of cases of pyelitis, all showing some dilatation of the renal pelvis, and in explanation said that they were cases of ureteral obstruction with secondary infected hydronephrosis I have some similar radiographs, but am inclined to think that the infection existed first and is the cause of the obstruction and the dilated kidney pelvis

S Mirabeau[8, 9] has written two excellent articles on ureteral obstruction He regards many such cases as due to infections of the lower end of the ureter, and strongly emphasizes the fact that in these the first attacks of renal pain are apt to be encountered at the menstrual period, owing to the pelvic congestion causing a swelling of the already inflamed ureteral mucosa and consequent obstruction

Most of these stricture cases are of long standing and slow progress and the first symptoms may be those of pyelitis, ureteritis or cystitis Unless the obstruction is great it may be some time before the ureter and the renal pelvis become dilated, and the kidney shows pressure changes If the narrowing is at the vesical end, there is ureteral dilatation before the renal pelvis is enlarged If at the upper end the pelvis and the calices become enlarged, and even in the earlier stages, as shown in the pyelograms, it is seen that the dilatation of the pelvis occurs in a downward direction As the ureter remains fixed, it first appears that it comes from the pelvis at a right angle, later it is seen in the so-called high origin, which has been given as a cause of obstruction instead of its effect As this becomes more marked there is seen the formation of a spur composed of the outer wall of the ureter and the inner wall of the pelvis, and this later acts as a valve I have in my possession the radiogram of a case that presented an enormously enlarged ureteral orifice as a result of the increased bladder-pressure from the tenesmus of a severe cystitis the ureter and the kidney pelvis were likewise dilated, and the relation of the ureter and the kidney pelvis are such as that just described This is detailed to show that the high insertion of the ureter and the formation of the spur or valve is the result of the pelvic dilatation According to Kelly,[5] these strictures involve from a few millimeters to one or more centimeters of the length of the ureter, and the rule is that they are apt to be extensive

SYMPTOMS

Usually there is a history of an antecedent pyelitis, ureteritis or cystitis, which may have occurred long before the symptoms of ureteral obstruction or have continued until the time the stricture symptoms appeared Garceau[4] has written an extensive article on ureteritis in which he states that besides pain along the course of the ureter, more especially at the pelvic brim, and frequency of urination, the presence of a large number of epithelial cells, singly and in plates, from the ureter is characteristic To obtain these without traumatism from ureteral catheterization he advises collection of the urine through a Kelly speculum with an oblique end and the patient in the knee-chest posture The pain of the ureteritis is often confounded with that of appendicitis and adnexal trouble, and many patients have been operated on for these conditions without relief of symptoms

In fact, it is often only after such operation that a true insight into the condition is found in looking for other causes for the patient's symptoms

After the definite formation of a stricture the symptoms become those of intermittent hydronephrosis, and are much the same as those caused by the sudden blocking of the ureter by stone, or kinking I think that the attacks are more severe, show a greater tendency toward periodicity, and that the symptoms are less noticeable between attacks than in cases in which the obstruction occurs from pressure of a tumor mass, the pregnant uterus or the extension of carcinoma

In most of the cases I have seen the symptoms have persisted for some time, in a few for many years At first the attacks are slight and far between, but in the course of time the intervals lessen, the attacks become more severe and last longer Exposure to cold, the drinking of water to excess, and the influence of menstruation have been given as determining factors of attacks, but it is only in regard to the last-named factor that I have noted any relation This is a point described by Mirabeau[8] I have had four patients who came to me for renal pain at the menstrual period, and while in only one did I demonstrate an obstruction with consequent dilatation of the ureter, I believe that these are cases of ureteritis that involve the lower end of the ureter and that sometimes they may progress to the formation of strictures

The pain of an attack is generally in the renal region, or may be referred anteriorly over the gall-bladder or the appendix It frequently comes without warning, is sudden, severe and often attended with nausea vomiting and eructation of gas There may or may not be bladder disturbances Oliguria during an attack with polyuria following, is often observed Chills and temperature depend on the presence of infection

The urine may show pus, small quantities of blood after an attack, casts from the nephritis that is often associated with marked ureteral obstruction, or as often is the case, the examination may be entirely negative

Even in moderate grades of hydronephrosis the kidney may show marked changes from pressure atrophy and a great falling off in its functional capacity In only three cases have we tested the functional capacity and in each of these it has been greatly decreased One was particularly instructive, it was that of a patient with only one kidney and a stricture of its ureter Unless the ureter is dilated to No 14 F every two weeks she has attacks of intermittent hydronephrosis.

Just previous to an attack her urine will be as low as eight or ten ounces and phenolsulphonephthalein 10 per cent in one and one-half hours with marked headaches and blindness Following dilatation the amount of urine is increased to 25 or 27 ounces and the phenolsulphonepthalein to 35 per cent in one and one-half hours This gradually falls as the stricture contracts, and the amount of urine decreases

While this condition may be suspected from the symptoms and before the appearance of renal tumor, we are dependent on cystoscopy, ureteral catheterization and radiography of the renal pelvis and the ureter after the injection of substances more or less dense than the surrounding structures. With the present methods of examination, especially pyelography, we should be able in practically all cases to make our diagnosis before the destructive kidney changes have become irreparable

Deficient kidney function may sometimes be determined on the affected side In attempting to detect strictures with the ureteral catheter we are often disappointed, for a stricture sufficient to cause serious trouble may not be felt with the smaller sizes and in the early stages the amount of dilatation and the consequent residual urine may not be enough to give a proper appreciation of the nature of the trouble The more extensive the stricture, the greater the dilatation above, the greater the value of the ureter catheter In the differential diagnosis of abdominal pains I feel that the pain caused by distending the kidney by injection through a ureteral catheter, if the same as that originally complained of, is most valuable But it only shows the probability of the lesion being in the urinary tract and does not determine the location and character of the trouble

In pyelography, as first suggested by Voelker and popularized in this country by Braasch, I believe that we have a certain means of diagnosing these cases, and in the early stages With this a graphic picture is obtained not only of the location of the stricture but of its extent, which makes it possible to form an opinion of the damage that is present above the stricture Without it I would have overlooked most of the cases that I have seen

Stanton[10] has recently written an article that points out more strongly than anything I have seen the necessity of careful examination of the urinary organs The stimulus for this was the number of cases seen at autopsy of marked kidney and ureteral lesions that could have been diagnosed during life, but which were not The records of fifteen general hospitals were then studied, and in those in which cystoscopy was used only when strongly indicated there was a percentage of 1 of operable cases of kidney and ureteral lesions Where cystoscopy with ureteral catheterization and pyelography, was frequent, this same percentage was 2

CASE REPORTS

Case 1—The patient, Mrs M, aged 65, was referred by Dr Madge McGuiness She had one child and one abortion The menstrual history was uneventful Previous history was negative Twelve years ago the patient began to have attacks of pain in the right renal region, associated with nausea, vomiting and the eructation of much gas For the first four years they came every six months and lasted twenty four hours Since then the attacks have increased in severity and frequency and for the last six weeks have come every six days, are of forty-eight hours' duration, agonizing and are not relieved by half grain doses of morphin at three hour intervals Many examinations of the urine showed no pus, no blood a few hyaline casts and many epithelial cells The specific gravity has ranged from 1002 to 1010

Examination—Cystoscopy showed nothing abnormal in the bladder Both ureters were catheterized, urine of low specific gravity with many epithelial cells and few hyaline casts was obtained from the right, that from the left was darker, of higher specific gravity and contained no abnormal structures Six mg of phenolsulphonepthalein were injected into the deltoid and appeared in the urine from the left ureter in ten minutes, but there was not a trace from the right after a period of twenty five minutes The catheters were both withdrawn and the urine collected from the bladder after two hours and mixed with that from the left kidney, the total amount was 35 per cent

Operation—March 23, a week after the examination, Dr Gertrude Kelly cut down on the right kidney, which she found somewhat prolapsed with many surrounding adhesions The kidney appeared as a tense cystic mass, with ureter coming off from the upper pole, and adherent to the renal pelvis An aberrant blood vessel was found running outward to the lower pole of the kidney, behind the ureter Nephrectomy was done Examination of the kidney shows that the renal pelvis had been dilated to the capacity of 45 c c, that the ureter was attached to the upper pole, was adherent to the pelvis, and that the lumen just allowed the passage of a small silver probe The renal structure showed pressure atrophy and is only 3/8 inch thick

---

[10] Stanton, Edwin McDonald The Journal A M A March 16 1912, p. 735

Pathologic Report—By Dr John E Welch "Sections through the cortex of the kidney show extensive degeneration of the tubular epithelium, and atrophy of the tubules The interstitial connective tissue shows marked hyperplasia, and over large areas completely replaces the tubules Here and there are areas of round cell infiltration, indicating an active inflammatory process The capsules of Bowman are very much thickened The glomeruli are atrophied and some of them are completely replaced by fibrous tissue The vessels are congested and the larger ones show marked thickening of all the coats There are numerous hyaline casts present in the collecting tubules and in places in some of the tubules of the cortex Sections through the pelvis show hypertrophy of the muscle elements, marked increase in the fibrous tissue, increase in the number of blood vessels and a slight infiltration of the whole wall by an exudate of leukocytes and more or less lymph The epithelium shows extensive desquamation Sections through the ureter show slight desquamation of the epithelial cells only Diagnosis Chronic diffuse nephritis and pyelitis"

Recovery was uneventful, the patient has regained her health and has had no more pain

CASE 2—The patient, Mrs S A K, aged 50, had an uneventful menstrual history with menopause at 47 She has four children, the oldest aged 22, and the youngest 9 years There was one spontaneous abortion at the third month fifteen years ago, but no subsequent trouble Twenty years ago she had some vaginal operation, and, following this, for two months, vesical tenesmus at the end of urination Five years later she had sudden attacks of pain in the right renal region radiating upward to the shoulder and downward along he course of the ureter These attacks lasted an hour and t first came on every three months, for a time she would have one on each successive day for three In the succeeding years the attacks became more frequent and the intervals shorter These attacks were not related to menstruation, nor did there seem to be any cause for them There were no bladder disturbances or changes in the amount of urine voided As a rule, the attacks came in the afternoon, though she has a number of times been wakened from a sound sleep by the pain

Examination—When first seen by me she was having the attacks every four or five weeks (June, 1911) She had had an operation in November, 1910, for gall stones and appendicitis with no change in her condition The urine was normal and the bladder showed no change The right kidney pelvis and the ureter were injected with 15 per cent collargol and radiographs were made that showed moderate dilatation of the renal pelvis, and dilatation of the ureter, with obstruction at the vesical end

Operation—A ureterovesical anastomosis was made, but failed For eight days the urine drained from the ureter through the vagina, which had been opened for safety drainage The ureter had pulled away from the bladder, but the urine from the right side emptied into the bladder through a fistulous tract extending from the end of the ureter to the bladder Two months after the operation the patient began to have pain constantly in the right side and the urine contained a large amount of pus The right ureter could not be catheterized on account of obstruction and tortuosity of the fistula As the patient would not permit another plastic operation on the ureter, the right kidney was removed on account of the existing suppurative pyelitis

Course—After this the patient did well until symptoms similar to those existing before the first operation arose in connection with the left side Since two months after the nephrectomy she has had very frequent attacks of the intermittent hydronephrosis unless obviated by the frequent dilatation of the left ureter It has been found necessary to dilate it with elastic bougies to 14 French every two weeks to prevent attacks Right after a dilatation the output of urine in twenty four hours will be about 25 ounces, and this becomes less and less and just before an attack will be near 10 I have made several phenolphthalein estimations at different times, and find that just after an attack about 38 per cent is eliminated in one and a half hours, and when an attack is imminent the output for the same time will be 10 per cent, this corresponding with the patient's elimination of urine and her general condition This ureter shows no tendency to remain dilated, and it is possible that a ureterovesical anastomosis will have to be done, or the ureter implanted on the skin if the collargol radiograph should show that such an operation as the first mentioned is impracticable

CASE 3—D H, aged 29, was referred by Dr M L Chard Her previous and menstrual histories were negative She had been married nine years and had one child 7 years old She was in good health until one year ago when she began to have attacks of pain in the right side, with nausea, but no vomiting She was operated on for appendicitis, but was not relieved, and in five months was again admitted to hospital with a history of frequent attacks of agonizing pain in the right upper quadrant of abdomen During the attacks she would fall to the floor and roll in pain Exploratory laparotomy showed stomach, gall bladder and cecal region free of any abnormalities Condition continued unimproved and now attacks come nearly every night

The kidney pelvis and ureter were filled with 40 per cent argyrol and radiographed There was seen a dilatation of the renal pelvis and of the ureter, with the point of obstruction at the vesical end The pain produced by the injection was the same as that complained of in her attacks There was no resistance felt to the passage of the No 6 ureteral catheter Patient refused to have anything done and went abroad

CASE 4—Sister F, aged 32, had a negative menstrual and other previous history The present trouble started one and a half years ago with pain in the right renal region radiating down the course of the ureter, associated with nausea, vomiting and eructation of gas The attacks came in the beginning at intervals of two or three months, and lasted two or three hours In the course of time, the intervals lessened and the attacks became more severe, at the time of examination they came every ten days, and lasted two or three days There was no urinary disturbance, though the patient had some increase in the amount of urine following an attack

Examination—The urine was negative Patient had lost much in weight and strength in the past few months Radiography of the argyrol injected into the renal pelvis and ureter showed some dilatation of the renal pelvis and an annular stricture of the ureter ¾ inch below the renal pelvis, opposite the tip of the transverse process of the third lumbar vertebra The injection gave the patient much pain of the same character as that complained of in her attacks, which lasted three days and was associated with moderate temperature

Operation—A plastic operation on the stricture was planned, but could not be carried out, so the kidney was removed The specimen showed the condition as diagnosed from the radiograph Two weeks after the nephrectomy the patient had an acute attack of appendicitis, in which the symptoms were not the same as those complained of in her previous attacks of pain, and the appendix, showing chronic catarrhal thickening, was removed Since these operations the patient has been relieved of her trouble and has gained much in general health and strength

CASE 5—Mrs W T, aged 40, was referred by Dr C C Guion, of New Rochelle Menstrual history was negative She has been married eighteen years and has one child 17 years old There were two spontaneous abortions at three months, the last twelve years ago Then she flowed for two weeks and was curetted, no trouble resulting After childbirth the patient got up early, and complained of pain in the left side of the back—lumbar region This did not trouble her much until five years ago when she began to have attacks of pain in the left renal region, associated with chills and fever These would last two days to a week During this time she noticed that the urine was cloudy, and often bloody She has had to get up five or six times at night to urinate, but for the past two or three months only twice Two weeks ago (history taken March 2, 1912) the patient passed some gravel She has been in bed for the past week on account of pain, chills, fever and sweats

Examination—The voided urine shows many red blood cells, few pus cells, 0 2 per cent. albumin (Esbach) and no casts Cystoscopy shows mild catarrhal cystitis, with marked redness around left ureteral orifice Both ureters were catheterized Urine from the left kidney showed moderate amount of pus and 0 2 per cent albumin, that from the right, numerous red blood cells and 0 1 per cent albumin Phenolsulphonephthalein, 0 6 mg, was injected, 25 per cent was eliminated in one hour from the right kidney, none from the left in the same time Radiograms of entire urinary tract showed two large stones in the pelvis of the right kidney

March 7 the left ureter was catheterized to the kidney pelvis, this second examination being done on account of the absence of the phenolsulphonepthalein, and 300 c c of urine collected in steady stream This relieved the patient of her pain and she felt better

An attempt was made later to pass a catheter into the renal (left) pelvis, inject argyrol, and make a radiograph, but an obstruction was encountered just below the renal pelvis that could not be overcome

Operation—March 22, through oblique lumbar incision, two large stones were removed from the right kidney through incision into posterior surface of pelvis The kidney was about two and a half times normal size, and white No attempt was made to close the incision in the pelvis A cigarette drain and layer closure were employed There was drainage through the lumbar wound for eighty hours, the drain being removed at the end of seventy two During the time the right kidney drained on the skin the daily amount of bladder urine was 12 ounces, after that 70 to 90 On the third day the patient became much nauseated, the next day restless and irrational, the next comatose and died uremic on the sixth No autopsy was allowed Had we been able to make a pyelograph more of the nature of the obstruction in the left ureter could have been determined

Case 6—Miss B, aged 50, was referred by Dr Arthur Booth Eighteen years ago after an attack of tonsilitis the patient had acute appendicitis, was sick two weeks and was treated radically After this she was much troubled with flatulency and obscure pains in the right upper portion of abdomen and right shoulder blade The patient was seen in 1900 by the late Dr Tilden Brown, who thought that she had a left renal tumor, the kidney could, under anesthesia, be displaced downward as low as the umbilicus In 1906, the chronically thickened appendix was removed, but nothing was done to the kidney as the patient took the anesthetic badly She was relieved of the flatulency and the pains in the upper right abdomen

A year previous to her operation for appendicitis she began to have frequency of urination, and, at times, bladder tenesmus, with occasional attacks of pain in both renal regions Since the operation, the right sided pain has almost entirely disappeared, but she is much troubled with almost constant pain over the course of the left ureter, lower half and frequent attacks of renal pain The patient voids urine every two hours during the day and gets up five or six times at night The examination of the urine has usually been negative, though on some occasions a small amount of pus and a few epithelial cells have been found

Examination—When first seen by me, April 2, 1912, the left kidney, not enlarged, could be displaced downward so that the upper pole was two fingers' breadth below the costal margin in the anterior axillary line, it could not be replaced entirely Cystoscopy showed slight general vesical hyperemia, most marked around left ureteral orifice The bladder urine showed few pus cells and few epithelial cells Collargol radiogram showed some dilatation of the left renal pelvis, the left ureter and an obstruction for a short distance above the vesical orifice The pain caused by the distention is similar to that she has during her attacks

On account of the reaction to instrumentation no attempt has been made to dilate this obstruction but efforts have been made to better the bladder condition by the use of argyrol and nitrate of silver bladder washings On two occasions 1 7,500 solutions have caused her renal pain, this has been noted in two other similar cases A nephropexy and a ureterovesical anastomosis above the stricture are contemplated

Case 7—M L. aged 30, a native of the West Indies, was referred by Dr Edward Quintard The patient has had malaria for a number of summers until the past two years She has three children, the oldest weighed 11½ pounds, difficult instrumental delivery There were two spontaneous abortions at three months but no subsequent trouble Wassermann and von Pirquet were positive

Examination—There had been no previous attacks of the present trouble Three weeks prior to admission to Post Graduate Hospital the patient began to have pain in the right upper quadrant of the abdomen which was almost constant in character A tender mass was to be felt just below the free border of the ribs in the mammary line, which was slightly movable with respiration There was tympany in front of this mass after gaseous inflation of the colon Temperature was 100 to 101 F Few pus cells were found in the urine from the right kidney No tubercle bacilli were found and there was no bladder disturbance

Treatment—The right ureter was catheterized and 40 per cent argyrol injected Radiograph showed some dilatation of the renal pelvis and a narrowing of the ureter at the level of the transverse process of the second lumbar vertebra The ureter comes off at nearly a right angle to the renal pelvis The character of the pain produced by the injection was the same as that complained of After the immediate discomfort of the examination the patient was better and relieved of her symptoms This case is considered as one of pyelitis with obstruction, the relief may have been due to the argyrol the dilatation of the narrowed ureter, or the combined effect

Case 8—S K, single, aged 22, was referred from Dr Edward Quintard's Medical Service at the Post Graduate Hospital Previous and menstrual histories were negative, von Pirquet was positive Trouble began twelve years ago with pain in the upper right quadrant of the abdomen, the pain being also referred to the right shoulder and scapula There was no icterus at any time The pain had no relation to eating Attacks at first came every few months, but of late had been every week Duration was one to ten hours There was no hematuria The urine showed many pus cells, but no tubercle bacilli could be found The right renal pelvis was injected with argyrol and radiographs were made, which showed some slight dilatation of the renal pelvis with a narrowing of the ureter just as it leaves the pelvis The ureter came off at nearly a right angle The injection caused pain similar to that complained of in her attacks Following this there was relief of symptoms, which we attempt to explain as in Case 7

CONCLUSIONS

Stricture of the ureter is more frequent than generally supposed, and is often diagnosticated as other trouble, especially when on the right side It is slow, progressive and leads to serious renal trouble The most frequent causes are of inflammatory origin, and the infection may be descending or ascending

In pyelography we have our most sure and accurate method of diagnosis, even in the early stages

393 West End Avenue

ABSTRACT OF DISCUSSION

Dr Guy L. Hunner, Baltimore It is very important in dealing with such an important organ as the ureter that we should know the original cause of the disease It may do little good to treat the local condi [illegible] in the ureter itself without treating its ca [illegible] especially interested i [illegible] tioned by Dr Furni [illegible] narrowing with an infection of the urinary tract with the result of a stricture at one of these congenitally narrow places That can be granted if all ureters are congenitally malformed, but we are not ready to grant this If, however, there is an inflammatory tract or stone in the ureter or anything to cause trauma at one of the points of narrowing the result is stricture at that point

Dr Furniss has drawn attention to the relative frequency with which we see acute kidney infection following disease elsewhere—following operation, furunculosis, typhoid fever or acute infectious diseases, tonsillitis, etc —and as I understand him, he says that most of the ureteral strictures are secondary to these infectious diseases elsewhere in the body I agree with him I wish to go further and state that some of these ureteral conditions occur without any infection, that is to say, they are lymphatic toxemias They come from some distant focus in the body In December, 1910, I showed before the Southern Gynecological and Obstetrical Association a series of cases of urethritis and ureteritis due to tonsillitis and I asked the members to bear the matter in mind and either disprove or prove my position Since then I have had a sufficient number of these cases of chronic ureteritis to feel thoroughly convinced that my standpoint in that matter is right, and that a large number of these cases of stricture of the ureter come from toxins of the tonsils Another thing rather pointing to the truth of that is the fact that a large percentage of cases are infected by the *Staphylococcus aureus* rather than by the colon bacillus, although the colon bacillus causes more than one half of the infections of the urinary tract.

We do not know much about the treatment No one has had enough experience yet to be able to state anything positive about it Cases of stricture near the lower end of the ureter seem to have a tendency to have a long section of the ureter strictured, whereas, near the pelvic brim and nearer the kidney, the strictures are likely to be annular This I think we shall be able to control by using bulb catheters and overstretching the strictures I am getting some positive cures of these annular strictures simply by that treatment With those having the long section involved near the bladder wall I believe it is necessary to go in extraperitoneally, cut them off above the seat of stricture and implant in the bladder I have not had much success in dealing with them Some can be dilated, but not all I had one just last week and the only thing I could get in was a little probe-like searcher After getting by the stricture, to get out again I had to bend the handle of my probe and push the Kelly clamp off over the probe and with one finger in the vagina pull as hard as I could The stricture was so dense that it had grasped the end of the probe Dilatation gives little hope We shall have to cut the ureter off and place it either in the bladder or in the kidney

Dr H D Furniss New York In my cases of stricture of the lower end of the ureter there has been little if any obstruction to the passage of small catheters, and most of them were diagnosticated by radiography after the injection of collargol or argyrol Otherwise we would have overlooked them except in the cases in which there was marked dilatation of the ureter above the stricture and retention of an appreciable amount of urine Cases of renal pain with purulent urine following a few days after operation, I explain as being due to infection of the renal pelvis and ureter, with consequent swelling of the ureteral mucosa and obstruction thereby to the ureter In these, pelvic lavage with silver nitrate has been successfully used As Dr Hunner states, obstruction of the lower end of the ureter does occur with pus free urine I think that the majority of these cases are in all probability due to lymphatic involvement of the vesical end of the ureter from a cystitis Dilatation of the lower end of the ureter is easy, but as Dr Hunner says, the results are unsatisfactory as the ureter will not remain dilated I have a patient whose ureter requires dilatation every two weeks When I return I shall inject argyrol, and make a radiogram to determine the exact site of the stricture and the amount of dilatation above In this case I contemplate making a ureterovesical anastomosis on account of the unsatisfactory results from dilatation The pain of the dilatation itself is not severe, but that following three hours afterward and lasting three or four hours is, this is, I think, due to the obstruction of the ureter following the trauma During the very painful period there is oliguria, which is followed later by a relative polyuria Ureteral obstruction in women is common, and pyelography is the most accurate method of diagnosis

A CASE OF SUSPECTED PULMONARY BLASTOMYCOSIS

John H Snoke, M D, and E J Strick, M D
Sio Khe, China

A Chinese woman, aged 36, came to the dispensary of the Neerbosch Hospital in March She was so weak and short of breath that she was unable to walk alone Our first impression was that this was a far advanced case of tuberculosis The patient was emaciated, anemic and very short of breath, she coughed almost constantly and raised large quantities of mucopurulent sputum Both apices and the left lung were normal There was an area of dulness about 5 cm in diameter just above the right mammary region in the nipple line Over this area were heard râles of nearly every description Patient complained of no pain, but of weakness and an inability to sleep on the affected side on account of coughing We examined the sputum as many as twenty times for tubercle bacilli but with constant negative results We noticed, however, the constancy of certain spore like bodies with double refractile capsules and granules This led us to suspect blastomycosis Up to this time, a period of about ten days, she had been taking emulsion of cod liver oil and hypophosphites with guaiacol Her fever ran from 101 to 103 and was more or less constant, except that there were evening remissions instead of the usual morning remissions The pulse was 112 and rather weak Under the cod liver oil and guaiacol treatment there was no change After we had decided that we were not dealing with tuberculosis but possibly with blastomycosis, we used copper sulphate as directed by Bevan[1] (quarter grain doses, three times a day) and the result was marvelous After twenty four hours the temperature had dropped to 99, and in three days it was normal in the evening, with a fraction of a rise in the morning, but within a week both pulse and temperature were normal, the constant cough was much relieved, and the quantity of sputum greatly reduced Its character, however, remained much the same The patient was soon able to sleep on the affected side and gained in weight and strength very rapidly We are sorry we have to report that some cough still continues and that we still find the blastomycetes in the sputum Nevertheless the patient has gained so much in the three months of treatment that she is able to walk four miles to and from the dispensary

Castellani[2] reports several cases which he calls bronchomycosis, the description of which answers quite closely to our own, but not entirely He claims cures by the use of potassium iodid in large doses three times a day

We have had ten cases of what seemed at first sight like tuberculosis, in the last three months, but the microscope showed tuberculosis in four cases, blastomycosis in five and one negative It would seem therefore that blastomycosis is not rare in China

The chief remedial agent employed successfully, says Ormsby,[1] is potassium iodid, first advised by Bevan The drug nearly always produces marked results and in some cases entirely cures the disease Doses as large as 600 grains a day are often required It should be given in large dilution and should be continued for a long time or until no renewed activity occurs after its withdrawal More recently Bevan has advised copper sulphate In our opinion these drugs are only palliative, and as yet we have no cure

---

THE RELATIVE VALUE OF THE "NATURAL" AND THE SYNTHETIC SALICYLATES

A STUDY OF THE LITERATURE*

CARY EGGLESTON, M.D.
NEW YORK CITY

There is at present a fairly wide-spread belief that the salicylic acid which is derived from the natural oil of wintergreen or sweet birch, and the sodium salt of this acid are to be preferred to the corresponding synthetic preparations. This preference seems to be founded mainly on two claims. The first is that the "natural" or "true" salicylates are less toxic than the artificial, the second, that they are more active as antirheumatic agents. The adherents of these views are very firm in their convictions, and, what is more, certain manufacturers make very positive statements regarding the relative superiority of the former compounds. On the other side of the question there are many who are equally certain that no such difference exists. A third class of physicians, those who are either neutral or who do not take a positive stand with either side, is probably greater than the two partisan groups combined.

If there is no difference in the toxicity or in the activity of the two classes of salicylates it is of considerable importance to know it, for the "natural" variety is about sixteen times as costly as the artificial. On the other hand, if the artificial is really more toxic or less active, or both, as is strongly urged, we would be unjustified in depriving our patients of the advantages of the superior drug or in subjecting them to unnecessary risk of unfavorable effects from the more toxic merely on the ground of economic difference. It therefore becomes an important matter to determine the validity of the several conflicting claims, if such be possible. The Committee on Therapeutic Research of the Council on Pharmacy and Chemistry of the American Medical Association has undertaken the solution of this question and will approach it from several points of view. The results of biologic investigation have already been published.[1] The results of chemical examinations and of therapeutic tests are forthcoming, and in this paper I shall attempt to review all of the evidence bearing on the question which can be found in the literature.

In the presentation of the results of my searches I shall endeavor to follow, as nearly as possible, a chronologic order, and for the most part I shall make use of literal quotations from the several papers, thus letting their authors speak for themselves and avoiding the danger of misconstruing their statements.

In 1874 Kolbe first described a means of manufacturing salicylic acid artificially from phenol. In 1876 Maclagan[2] suggested the use of salicin in the treatment of rheumatism, based on the conception that rheumatism was, as malaria was then supposed to be, miasmatic in origin, and that salicin, like cinchona, was a natural remedy, found growing in the regions in which rheumatism was most prevalent. From about 1875 on, the literature on the beneficial action of one or another of the salicyl preparations in rheumatism grew apace and along with the favorable reports came the records of untoward symptoms resulting from the new therapy, but it is not until 1877 that one finds any definite comparison of the artificial acid with the acid derived from the oil of wintergreen or from salicin.

In that year Williams[3] read a paper on the impurities of the artificial acid, which he ascribed to the presence of impurities in the parent phenol. He described a method by which he was able to purify the artificial acid so completely as to obtain an acid identical in every way with the natural product. He thought that the impurity was probably a derivative of cresol (cresylic acid) and of this he remarked:

> Respecting the medicinal properties of this acid I can say nothing as yet, it may be, like paroxybenzoic acid, inert, and would then be simply a diluent of the salicylic acid, or it may be active as an antiseptic, or it may be mischievous. ... whatever it be there can, I think, be no doubt that the artificial salicylic acid at present used for medical purposes is not so pure or so uniform as is desirable, and that it should be more highly purified and freed from this second acid I have described before it or its salts are used in medicine.

In the discussion[4] of Williams' paper Professor Redwood is cited as saying:

> Mr. Williams has done a great deal toward affording the explanation of a fact which many had been aware of, namely, that the artificial salicylic acid sometimes failed in producing the effects anticipated, such as would be produced by the natural acid.

Mr. Plowman confirmed fully the statement that artificial salicylic acid frequently caused considerable derangement to the system. It had been given in St. Thomas' Hospital in doses of 20 grains every two hours and the results had frequently been to cause delirium. He was uncertain, however, whether the acid used was artificial or not, but from the price paid for it he thought that it was probably artificial.

In 1879, 1880, 1882 and 1888, the *Lancet* contained papers by Maclagan defending his stand with regard to the superior antirheumatic action of the natural salicylates as exemplified by salicin. His contentions were strengthened by occasional reports of the unfavorable effects of the impure artificial acid and its salts and it would seem that his views which referred the action of salicin to its presumed "natural relation" to rheumatism gained wide support and are, perhaps, to day at the bottom of a similar idea regarding the difference between the actions of the "natural" salicylates and those of the artificial.

Following Williams, the next paper to appear bearing on the question was one by Fowler[5] in 1881 from which I will quote:

> In thirty-nine cases treated with pure salicylic acid [natural] toxic symptoms were present in ten only. In five there was deafness, in two deafness and tinnitus, in three deafness, tinnitus and vomiting. ... As regards the relief from pain, subsidence of fever and liability to relapse, the pure acid does not appear to act with greater benefit than the ordinary [artificial] acid. ... The advantages claimed for the pure acid are that it rarely produces vomiting and never delirium.

He also remarks that investigations which are going on show an impurity in the artificial acid, not, as yet, identified.

Fowler's observations are too few to permit of very definite deductions but it is to be noticed that his short series showed vomiting in 7.5 per cent. of the cases

---

* This investigation was undertaken at the suggestion of the Committee on Therapeutic Research of the Council on Pharmacy and Chemistry of the American Medical Association.

* From the Department of Pharmacology of Cornell University Medical College.

[1] Waddell: Comparative Investigation of the Effects and Toxicity of Sodium Salicylates of Natural and Synthetic Origin, Arch. Int. Med., December, 1911, p. 784.

[2] Maclagan: Brit. Med. Jour., 1876, i, 627.

[4] Pharm. Jour. and Tr., 1877-78, viii, 798.

[5] Fowler: Lancet, London, 1881, ii, 1118.

This does not agree altogether with his further statement that one of the advantages claimed is that the "true" acid, "rarely produces vomiting" This percentage may have been a "rare occurrence" of the symptom as compared with what was seen after the use of the artificial acid which was then on the market His evidence in favor of the "true" acid is, then, not very strong, for he finds no difference in the antirheumatic powers of the "true" and the artificial acids, and his incidence of vomiting from the "natural" is by no means low

Broadbent[6] expresses the belief that when toxic symptoms arise they are due to an impurity in the artificial drug He says

> A question which we have not been able to resolve—indeed, I do not know that the material exists for its determination—is the relative advantages of the different salicyl compounds It seems to me that the "natural" salicylic acid, as being less liable to contamination than the samples made from coal tar compounds, is preferable to the latter, and it is a matter for inquiry which no doubt will be submitted to the test of experience, and which certainly I, for one, shall endeavor to elucidate.

Broadbent was a man of very wide experience as an internist and therapeutist, and yet he was able to offer no *evidence* regarding the relative merits of these two acids But his suggestion that it would be better in all probability to employ the "natural" must have had some weight in influencing many of those who looked up to him for guidance So far as I have been able to discover he did not publish anything further on the subject

Latham,[7] who was probably looked on as the greatest English authority on rheumatism in his day, laid down the following rules to ensure success in the treatment of that disease

> First, *the true salicylic acid obtained from the vegetable kingdom must alone be employed* If you have to give large doses avoid giving the artificial product obtained from carbolic acid, however much it may have been dialyzed and purified An impure acid will very quickly produce symptoms closely resembling delirium tremens Secondly, give the acid without any alkali or base Thirdly, place the patient fully under the influence of the drug—that is, let him have sufficient to produce cerebral disturbance—that is, buzzing in the ears or headache, or slight deafness

These statements are dogmatic and made without reservation, and are presumably based on the results of his clinical observations Unfortunately, however, he cites no single case in substantiation of his statements The reference to dialyzation and purification of the acid relates to the attempts by Dr E R Squibb and others to remove the impurities from the artificial acid by dialysis They claimed thus to produce a perfectly pure product, but it was subsequently shown that the impurities were not colloidal and that they dialyzed readily, so that the resulting product still contained much of the original impurity Latham mentions no disadvantage of the artificial acid other than the production of delirium, and his subsequent remarks calling for the use of enough of the "true" acid to cause cerebral symptoms such as tinnitus, deafness and headache strongly suggest that if the "true" acid were carried farther in its use, it, too, might have given rise to dilirium He does not compare the efficacy of the two acids nor does he speak of the effects of the two on man in similar doses His views must have been of great weight at the time, but his failure to present the evidence on which he based his remarks detracts materially from the scientific value which can now be attached to them We do not know from him that the "true" acid did not also produce unfavorable symptoms at times We do not know that he ever used the artificial acid as a control All that we do know from him is that he strongly advocated the choice of the "natural" acid, why, he does not tell us, save for the mention of the delirium The first experimental work done on the determination of the relative advantages of the "natural" and artificial salicylates was that by Charteris and Maclennan[8]

It is not within the scope of the present communication to discuss the details of these experiments or to challenge their conduct, I shall deal only with the conclusions that have been drawn from the results they obtained and will refer the reader to an article by J A Waddell[1] for detailed consideration of the individual experiments

From their experiments they make the following deductions

> These experiments prove that salicylic acid obtained naturally by oxidation of salicin, or from the oil of wintergreen, in 10 grain doses, has no deleterious effect, that salicylate of soda obtained from the natural salicylic acid, in 32 grains, is not lethal, but that it causes prostration and lowers the temperature
>
> On the other hand, it is conclusively demonstrated that salicylic acid, artificial, in a 10 grain dose, causes first, paralysis of flexors, secondly, death by violent convulsions Sodium salicylate, artificial, in 18 grain doses, is lethal
>
> The deductions from these experiments indicate that artificial salicylic acid and its salt of sodium are dangerous and in large doses fatal to animals, while natural salicylic acid and its salts of sodium are not

They believe that this difference depends doubtless on *some impurity in the artificial acid* This conclusion is strengthened by a letter which they received from G G Henderson of the chemical laboratory of the University of Glasgow, giving the results of his examination of samples of the two acids used by the authors He found that the artificial was impure, containing "a small quantity of another acid which I have no doubt is the cause of the appearances observed after the use of artificial salicylic acid" Further, he says, "I should add that no trace of this substance is to be found in natural salicylic acid"

Subsequently Henderson isolated this impurity and Charteris and Maclennan tested it, finding that "the action of this impurity seems to be of the nature of a slow but certain poison, and the lethal dose is relatively much less than that of salicylic acid"

They close their paper with the following

> The obvious conclusions from these experiments are that artificial salicylic acid contains an impurity or impurities, and until this or these can be extracted by the aid of chemistry the internal administration of it or its salt of sodium should be discountenanced. Large and repeated doses of the sodium salt are necessary in the treatment of acute rheumatism, and hence we may account for the restlessness, the confusion, and the delirium sometimes attendant on its use, which have been testified by clinical experience It is more than probable, too, that the retarded convalescence occurring in some cases of acute rheumatism after the salicylate treatment is due to the great and protracted prostration which the impurity or impurities give rise to It is to be remembered in connection with these symptoms that prescriptions of the salicylate of sodium are invariably made up, unless

[7] Latham Brit Med. Jour 1886 i 735 (Croonian Lectures)

[8] Charteris and Maclennan Brit. Med. Jour 1880 ii 1208.

otherwise indicated, from the artificial and not the natural salt[9]

The first criticism of the work of Charteris and Maclennan is that they have drawn far-reaching conclusions from decidedly insufficient evidence They made only three experiments with sodium salicylate, one with the artificial and two with the "natural", and only two tests of the salicylic acid, one with each variety Further, as remarked by Waddell,[1] all of these tests seem to have been made on but two animals, one for the "natural," the other for the artificial In addition, it is obvious that they tested the action of only one specimen of each of the preparations They therefore made no controls of the reactions of the animals they used, and established a lethal dose as the result of a single test The specimens of the preparations which they employed may or may not have been representative of what was to be found on the market at that time And yet from these experiments on but two animals they offer without hesitation the explanation of many of the untoward symptoms seen at times during the therapeutic administration of the drug to man

If their statement is correct regarding the dispensing of the artificial preparations, then how many of those who have reported favorably on the beneficial effects of the salicylates, without any specification as to which class of preparation they were using, have been, in fact, reporting the salutary action of the condemned artificial products? On the other hand, if Martindale and Squire are correct, how many of the unfavorable impressions relating to the action of the salicylates have been founded on the action of the "natural" preparations? The numbers were legion of these two groups of reports which appeared at about this time and in which there is no mention made of the source of the preparation

Thus far Charteris and Maclennan's case in favor of the "true" salicylates is none too strong, we shall hear more of their work later

The discussion[10] of the paper by Charteris and Maclennan contains some points worthy of our attention Dr Shaw remarked that "all the evil effects generally attributed to the action of salicylate of soda were not due to extraneous causes It was not only on account of price that it was preferred to salicin, as it was a more efficacious drug He had seen delirium and hemorrhages following the use of salicin as well as after salicylate of sodium"

Haig said that he thought that the toxic effects of sodium salicylate had been exaggerated, but that there was a great difference in the different specimens Taylor said that he gave 20 grains of sodium salicylate [artificial] every two hours and found delirium by no means uncommon Myers "could not agree with the great danger of producing toxic effects with that drug" [i e, artificial sodium salicylate] Bruce said that he could not agree with Taylor, for he had rarely seen delirium, though he gave 15 grains or more every three hours He thought the drug then in use finer than formerly, for toxic effects were rarely seen

Shaw's remarks indicate that he considered many of the unfavorable effects of salicylate administration as due to the action of the salicylate itself and not to the presence of impurities derived from the phenol in the process of synthesis He certainly implies this construction when he further adds that he has "seen delirium and hemorrhages following the use of salicin as well as after salicylate of sodium"

Haig's statement to the effect that there was a great difference between different specimens of the artificial salicylate of soda serves to strengthen the similar suggestion, which I made in discussing Charteris and Maclennan's results, that the specimens which they used may or may not have been representative of what was to be found on the market at that time

Taylor's dose of the drug is rather high and it is not impossible that a similar amount of the "natural" salt would have produced a like result, for in the paper by Latham,[7] he advises that sufficient of the "true" acid be given to produce cerebral disturbance," and subsequently says, "In the majority of cases 80 to 100 grains are enough' It takes approximately 115 grains of sodium salicylate to yield 100 grains of salicylic acid so that, given in doses of 20 grains every two hours, only six doses would more than correspond to 100 grains of the acid In addition Haig, Myers and Bruce could not agree with the experiences of Taylor

The experiences, then, of those who discussed the paper of Charteris and Maclennan tend, if anything to oppose the idea of greater toxicity of the artificial salicylate of sodium, and to refer such unfavorable effects as are seen to the action of an excessive amount of salicylate, regardless of its source

We now return to Charteris[11] and quote from a second paper of his in which he says that "there has been a steadily growing conviction that artificial salicylate of soda is depressing, and further that in certain cases there is cerebral excitement culminating in delirium " He cites the experiments which he had described in the preceding communications He then relates having tested two samples of supposedly "pure" artificial acid on rabbits, and 15 grains per 2½ pounds were found to be fatal

Next, he cites Williams, whom I have already quoted[3] He followed Williams' directions for the purification of the artificial acid, preparing a pure salicylic acid which had the appearance of the "natural" and a similar melting-point He made three tests on rabbits with this purified acid and found that "the result was most satisfactory", "that there was no paralysis and no depression but that, on the contrary, the animals were neither up nor down, but were able to run about with ease after the last injection"

As a result of these experiments he remarks that "these facts show that the process of purification, even on a small scale, is not tedious or difficult, and in all probability it could be done easily and thoroughly on a large scale with less loss of time, and at only a slightly increased cost, as compared with the present method [1890]"

Up to 1890, he says

> So far we had found none [i. e no specimens of artificial salicylic acid] able to stand the physiologic test
> But on Jan 1, 1890, unsolicited, a Berlin firm communicated with me through their agents in London This firm sent specimens supposed to be chemically pure, but when tested they were found to be not quite so, though relatively so Since then specimens of acid have come from the same firm which give the same physiologic action as that from the natural salicylates

He concludes by saying, "F[illegible] in medicine they [pharmaceutical che[illegible] large crystalline form of the artificial acid, and from this alone should the salicylate of soda be prepared" Charteris had previously described the chemical and physical characters of the "natural" acid and of the completely purified artificial product The two were the same

---

[9] In the same volume (Brit Med Jour 1889 ii 1315) Mr Martindale writes in regard to this statement regarding the filling of prescriptions The reverse is the rule with all good dispensing establishments in London Messrs Squire & Sons confirm Martindale s statement.

[10] Brit. Med Jour, 1890 i 350

[11] Charteris Med. Chir Tr.,

The results of this second set of observations by Charteris tend to show that the deleterious actions of the artificial acid were not inherent in the acid but were wholly dependent on the presence of an impurity, a view suggested by most of the preceding authors, but, until now, not definitely established They further show that it is quite possible so to purify this acid as to obtain a product having the physical, chemical and pharmacologic characteristics of the "natural" product That this process of purification is neither complicated nor unduly costly seems to have been demonstrated by his work Lastly the commercial purification of the artificial salicylate seems to have been accomplished to the extent of yielding a product in no way different from the "true" acid These results, coming from one who formerly was so powerful an advocate of the use of none but the pure "natural" product, are the more convincing, for there can be no contention of blind adherence to a preconceived notion.

Charteris must certainly have convinced himself most firmly of the similarity between the completely purified artificial acid and the "natural", of the equal efficacy of this purified product and the "natural", and of the purity and efficacy of the sample of the commercially purified product, before expressing conclusions so diametrically opposed to those which he had previously expressed

The objection may be raised here that his methods were not checked up by control experiments in this latter work any more than they were in the former This objection has lost much of its validity, for at the time of this report he had made tests similar to the earlier ones on a much larger number of animals and with a considerable number of specimens of salicylic acid Each test thus made served, in a measure, as a control for the succeeding Nevertheless, it is regrettable that he still contented himself with a few tests when he might have made his evidence vastly more valuable had he but doubled or trebled their number

In the same year that this last communication of Charteris' appeared, Dunstan and Bloch[12] published a paper in which they entered into a consideration of the chemical side of the relative purity of the two acids and discussed means of purification They say

> Therapeutic observation has, however, disclosed the fact that both the commercial salicylic acid and that purified by dialysis produce effects when administered to the human subject which are not observed to result from the administration of the pure salicylic acid, prepared from the methyl salicylate contained in the natural oil of wintergreen

They cite several observers who found from 6 5 per cent to 30 or 40 per cent of impurity in the commercial acid of that time

They further remark, "It will be seen that the toxic action of the artificial salicylic acid of commerce has been definitely traced to an impurity "

They found ortho- , meta- and paracreosotic acids in the specimens which they examined

In the same volume[13] there is a report from Charteris on the results of biologic tests of these creosotic acids on rabbits He found the ortho- and para-acids highly toxic to these animals [two animals, one for each of the acids] Metacreosotic acid was non-toxic He further made two tests on rabbits of purified artificial salicylic acid and found it to give satisfactory results, i e that it was not toxic

To quote

> The ortho and paracreosotic acids by their physiologic action show that they are slow but certain poisons, causing prostration and paralysis affecting first the hind limbs and gradually extending over the body
>
> The well defined crystalline form of the acid [artificial salicylic] with a melting point of almost 157 C, should be the official form of the artificial salicylic acid, and from this alone should the salicylate of sodium be prepared
>
> I may add that if salicylic acid be prepared from synthetic carbolic acid, having a melting point of 42 C, it then contains no impurity Its melting point is 157 C, and, its physiologic action is in every way satisfactory

There is a fuller presentation of the same paper by Charteris in the *British Medical Journal*[14] from which I quote his closing remarks

> sufficient evidence has been adduced to show that in cases where poisonous symptoms have been evoked by the administration of large and repeated doses of the artificial salicylate of soda in rheumatism, they are dependent on its containing the impurities mentioned [that is, o and p creosotic acids] Further experiments may be necessary to determine whether the amount of paracreosotic acid contained in some samples of commercial salicylic acid is sufficient to produce poisonous effects on a human subject My experiments show that when injected into small animals it is poisonous, though in a less degree than the ortho acid, and that its poisonous effects are intensified when combined with the ortho acid, and still more so when incorporated with this acid and salicylic acid

Regarding the sodium salt of paracreosotic acid he says that " judiciously given, [it] may be of benefit in certain diseases "

These three communications, the one by Dunstan and Bloch, and the two by Charteris, serve further to establish the fact that the unfavorable actions of salicylic acid and its sodium salt, derived synthetically, are not inherent in these preparations but are due solely to the presence of impurities which it is quite possible to remove completely They further confirm the previous work which showed that the artificial salicylates when efficiently purified are physiologically identical with the corresponding "natural" salicylates

In spite of the work done by Charteris it is difficult to accept his contention that paracreosotic acid is so much to blame for the production of the toxic effects as he says it is, for he himself admits that its sodium salt has been used in therapeutics In Germany at about this time sodium paracreosotate [paracreosotinate] was in use in medicine and did not cause any severe toxic symptoms when given in doses of 5 grains each Further, in the light of the work of Waddell,[1] we are almost forced to reject this idea Waddell has also shown that "mixtures of paracreosotinate of sodium with natural sodium salicylate do not exhibit greater toxicity than the components " This contradicts the previous statement made by Charteris regarding their combined action Further, in a letter to the *British Medical Journal*[15] Professor Stockman takes exception to the contention that the toxic impurity of artificial salicylic acid is creosotic [creosotinic] acid In this letter he says

[14] Charteris Brit Med Jour, 1891 i 695

[15] Stockman Brit. Med. Jour, 1890 ii 1271

> That this substance is not creosotic acid seems to me to be proved by the following considerations.
>
> 1. The results of clinical experience with creosotate of sodium, it was used by Buss (1876) in doses up to 4.0 gm., by Gatti (1879) in 5.0 to 8.0 gm. doses, and by Demme (1889) in children up to 1.5 gm. None of these authors observed that it had any particular poisonous effects, and they agree in concluding that its action is practically identical with the action of salicylate of soda. It will be observed that Demme used paracreosotic acid, which is stated by Professor Charteris to be so poisonous that 2 grains of it killed a rabbit weighing 1½ pounds.
>
> 2. The chemical constitution of creosotic acid. Chemically it is very closely allied to salicylic acid, and from what we already know of the relationship in physiologic action among the members of this series, one could predicate with certainty that in action it would closely resemble salicylic acid.

Stockman is of the opinion that the specimens of creosotic acid which Charteris tested also contained the same unknown impurity as did the salicylic acid he had previously tested.

May[16] cites the same observers as have just been mentioned in the quotation from Stockman. He notes that Demme gave 90 to 120 grains of paracreosotinic acid to men without the production of toxic symptoms. May conducted some experiments on man and animals with the several creosotinic acids [creosotic] and concludes by saying:

> The creosotinic acids resemble salicylic acid in their action as antifermentatives, as bactericides, as antipyretics, and as specifics in acute rheumatism. Their toxic effect in animals is about the same, but orthocreosotinic acid is more depressing to the circulation.

These remarks by May and Stockman merely throw doubt on the accuracy of the determination of the precise chemical nature of the body which was the cause of the deleterious action of the salicylic acid which Charteris used and the truth of the remarks of Stockman were, in turn, challenged by Dunstan. It would carry us too far afield to consider this phase of the problem. All that concerns us at the present moment is the question of the purification of salicylic acid and the action of the purified product.

Taking cognizance of these differences of opinion and the objections to Charteris' conclusions, we have not impaired the validity of his work with regard to the lack of toxicity of the purified artificial salicylates. And the number of experiments which he had by this time done with the purified products is sufficient to remove the objections on the ground of possible idiosyncrasies on the part of his animals.

I might here make brief mention of Henderson's[17] observations on the question of the purification of salicylic acid. He tried many methods and found that the very simple one devised by Williams[3] was the most satisfactory. He found as impurities creosotic acid, parahydroxybenzoic acid, and hydroxyisophthalic acid. He remarks, "It is therefore a comparatively simple matter to manufacture a pure salicylic acid—indeed, I understand that this is now being done." (1890.)

Stockvis[18] seems to have been about the only man outside of Great Britain to make any studies on the relative advantages of the artificial and the "natural" salicylates. He cites the paper of, "Chartens and Machyon," which is obviously intended as a reference to that of Charteris and Maclennan. Stockvis used the sodium salt of each of these acids.

His findings were, in brief, that the "natural" was much milder in its actions than the artificial, that the "natural" acid was excreted the more rapidly in the rabbit and man, that with the more rapid excretion of the "natural" there was a marked diuresis in addition (this was not true of the artificial), and that, in the same doses, the actions of the "natural" were less marked on the rabbit than those of the artificial, but that the lethal doses were quite the same. On frogs' hearts the salicylates caused depression, smaller doses of the artificial being required than of the "natural." He cites the experience of Moerel, who took the drug daily for fourteen days in doses of 0.2 gm. every four hours [about 3 grains four times a day]. On the first day he observed headache, which soon passed off, there was no effect on sleep, appetite or other function. The temperature was little altered. These symptoms were less marked in the case of the "natural" product. The pulse-rate was somewhat increased by the artificial and less by the "natural." Respiration was raised in rate by the artificial, and practically not at all by the "natural."

Taking all of the results together, Stockvis remarks that there is hardly to be noted any qualitative difference in action between the artificial and natural. He says that one must agree unconditionally with "Chartens and Machyon" that the difference is merely quantitative, and that the natural is the less toxic. That in the explanation of this difference the more rapid elimination of the natural plays a great part, this he attributes to "osmotic peculiarities" of this acid. He found that the electrical conductivities of the two acids were not identical, and that the "natural" was impure chemically, being mixed with an extremely small amount of oil of wintergreen. He said that our next task would be to free the natural acid completely from the methyl-salicyl-ester and make comparisons of this with the pure artificial acid.

He concludes with the remark that "so much is evident, that the chemically impure 'natural' acid is better therapeutically than the chemically pure artificial."

In view of all of the previous work one cannot be but struck by Stockvis' conclusion that the *milder* actions of the "natural" salicylates are due to their *impurity* while the artificial compounds are pure. Such a view must be taken with considerable reserve, for it is opposed to all of the chemical and pharmacologic studies which we have thus far reported. In his work there is a further rather anomalous statement to the effect that though the "natural" salicylates were found to be "less marked" in their actions than the artificial, the fatal dose was the same for the two forms. When we recall that he also said that "there is hardly to be noted any qualitative difference" between the two, and that "the difference is merely quantitative," we are at a loss to know how to reconcile two contentions so completely antagonistic.

It may be true that the "natural" gives a greater diuresis than the artificial, but just how this explains the "milder actions" of this product is by no means clear, particularly in the experiments in which the drugs were applied to the frogs' hearts. Why this diuretic effect of the "true" reduces its actions to a less marked grade and does not similarly effect its lethal action is also difficult of comprehension.

The evidence brought forth by the self-made observations of Moerel is not convincing, for the differences he experienced in the effects of the two salicylates are so slight as to be accounted for as being the results of the psychic influences of a preconceived idea. Finally Stockvis' failure to look further into the literature of the subject than the earliest work by Charteris accords with the general superficial character of his observations.

Lewin[19] adds nothing to what has already been discussed, but he repeats that the impurities of the artificial salicylic preparations are responsible for their side actions, such as delirium and cerebral excitement. While this is true regarding the difference between the actions of the two classes of salicylates, he remarks that it must be borne in mind that pure preparations are not devoid of side actions. These impurities are probably the ortho- or paracreosotic acids. His work is not original. It is merely his summary of the literature, with the stamp of his interpretation of the value of the several ideas suggested. I introduce this merely on account of the fact that what appeared in Lewin's book must have had some influence in molding medical opinion on account of the reputation of the author.

Along with the preceding it may be well to cite the monograph by Pribram,[20] in which he reviews at length the greater part of the literature relating to the salicylate therapy of rheumatism. He details a very formidable array of unfavorable effects of the salicylates, without mentioning whether they resulted from the "natural" or the artificial, and then remarks that it is obvious that many of these phenomena, including death, were probably in no way attributable to the action of the salicylate, on which the blame was thrown.

The first of the American papers to deal with the question of the relative merits of the two forms of salicylate seems to be that by a pharmacist, Cone.[21] His evidence is composed of citations from some of the authors whose work I have already discussed, and from some whose papers I have been unable to find, as Cone gives no references. Among the latter is one from Dr. H. M. Lyman, who said, in an address, that he had had the following early experiences with the use of salicylic acid and sodium salicylate: he "found that the results were not so good from preparations made in this country as from the original German article, due to impurities in the former." He reports a case of delirium tremens-like symptoms from its use.

Dr. Simon Baruch is cited as saying that to get the effect from the salicylates without their inconveniences, pure salicylic acid should be used; only that derived from the oil of gaultheria should be employed.

Dr. Abraham Meyer is reported as saying that only the salicylic acid from genuine oil of wintergreen should be used; that the others [i. e., the synthetic and the salicylic acid derived from the synthetic oil] cause disturbance of the stomach, and delirium.

After citing the work of Charteris and Maclennan, of Dunstan, and Charteris' second paper, Cone goes on to discuss the tests for purity and their ability to detect adulteration. He concludes as follows:

> At present a very large percentage of the oil of wintergreen on the market is adulterated, mostly with the synthetic methyl salicylate, and this adulteration has been the most difficult to detect, possessing as it does, about the same chemical composition and with physical characteristics nearly identical.

Pancoast and Pearson[22] also have entered into the study of the purity of the salicylic acid sold as "natural," and, though it breaks the chronologic order, I shall bring in their findings at this point and discuss the two papers together. They say:

> Since the so called natural salicylates have met with such wide spread favor as therapeutic agents, there has been a tendency on the part of a few unscrupulous distillers, dealers and drug merchants, to substitute the low priced synthetic products. This tendency has more rapidly grown as there has been no accurate means of detecting the sophistication.
>
> For some years chemists have endeavored to detect the presence of synthetic methyl salicylate when added to oil of birch or gaultheria, but, owing to the great similarity of these products, the task has been very laborious. All three of these products contain at least 99 per cent. of absolute methyl salicylate.

While these two papers from pharmacists add very little of value from the clinical or experimental aspects of the question, they are of interest because they serve to show how slight the chemical differences between the "natural" and artificial salicylates are—not over 1 per cent. according to one—and how difficult it is to be certain that one really has the "natural" product, and not, in fact, a combination of the two. This suggests a little doubt as to whether all of those who have praised the "natural" salicylates so highly have in reality been using the drugs they lauded, or only mixtures of "natural" with the artificial. This applies particularly to the clinical reports, for in most of these the question of purity of the product was not investigated. The vast difference in the price of the two classes of salicylates makes adulteration far more probable than not in many instances. It is not improbable, then, that many have unwittingly sung the praises of the artificial in the belief that it was the pure "natural" salicylate.

The last three papers which I shall present are from American authors and are purely clinical in character, hence they are subject to the criticisms which I have just made regarding the possible impurity of the products used. It is certain that the authors were sincere in their beliefs that what they used was only the "natural" salicylate, but who is to check the purity of the salicylate that the local pharmacist uses in preparing the prescription? Even if he be acting in good faith, it is not probable that he can be any more certain of the purity of the preparation that is sold to him than is the physician of that he receives from the druggist.

The first of these papers is by Dr. Winters,[23] in it he speaks of the salicylates only in the course of the discussion of the treatment of rheumatism. He says that there is a positive chemical antidote to rheumatism and that "this antidote is an *organic* chemical compound. Synthetic salicylic acid has no effect." He gives no data on which he bases these statements. This is the strongest support of the "natural" salicylic acid and the most severe condemnation of the synthetic that I have found.

The second is based on the observations of Rosenzweig and Ronginsky.[24] As the result of some clinical observations on the artificial and "natural" salicylic acids they reported, "The 'natural' product does not depress the heart as much as the artificial product; it does not upset the stomach so much; it acts more rapidly." Like the preceding author, they do not give the data on which they base their statements; the statement quoted above was, in fact, reported as coming from them by a third person, Dr. Kahn, who had asked them to make the observations This kind of evidence is certainly far from convincing and has no scientific value

[24] Rosenzweig and Ronginsky: Quoted by Kahn in Druggists Circular, 1908, lii, 345.

The third of these papers is by Dr Lambert,[25] in which he strongly advocates the use of the oil of sweet birch in preference to the synthetic salicylates, and in fact in preference to any other of the salicylates He bases this on clinical experience and while he thus advocates the use of the "natural" salicylates, he does not by any means exclude the usefulness of the artificial, for he specifically says that if one of the common forms of salicylate does not agree with the patient we should try others until we find one that does " if the patient is resistant to that [true oil of birch], it should be changed to some other form of salicylate"

It does not seem necessary to enter into a separate discussion of the last three papers, for such of the previous criticisms as apply would only have to be repeated

Before summarizing it may be of interest to cite from two personal communications from Professor Stockman of the University of Glasgow to one of the members of the Committee on Therapeutic Research of the Council on Pharmacy and Chemistry From the first, written in October, 1911, I shall quote

> Some years ago I examined five samples of artificial sodium salicylate from different manufacturers I found that four of them were *practically chemically pure*, and *differed in no way as regards clinical action*, and *chemical tests from the "natural"* sodium salicylate[26] So far therefore as my own experience goes I regard the matter as settled

He further says that "gross differences certainly do not exist between the actions of pure artificial sodium salicylate and the so-called 'natural' product" In a second communication he says that he has gone into the question of the "natural" and synthetic salicylates and he has "found that the pure synthetic acid is not more poisonous than the other ('natural')" He also finds, as a result of therapeutic examinations, that creosotic (creosotinic) acids "can be given in doses similar to those of the salicylates"

Before drawing any conclusions from the material which I have been able to collect as bearing in any way on the question of the relative value of the artificial and "natural" salicylates, I shall briefly summarize the evidence brought forth in the papers and discussions which are here presented

There is first the clinical evidence I have been able to find only fourteen expressions of opinion from the clinical point of view favoring the "natural" salicylates over the artificial One of this group (Maclagan)[2] speaks only in favor of salicin, and his reasons for his views go far to invalidate his contentions A second (Charteris) favored the "natural" in his first paper only, and subsequently specifically advocated the use of the pure artificial salicylates A third (Lambert) favors the "natural" but does not condemn the artificial, using it when the "natural" is ineffective The rest of those who favor the "natural" salicylates in general give no evidence in support of their contentions, merely stating their views more or less firmly Two do give clinical evidence for their contentions (Fowler and Stockvis), but in neither case is the evidence at all convincing Only two (Maclagan, Winters) have challenged the therapeutic value of the artificial salicylates

Second, there is the chemical evidence This is of a positive nature and the findings are, in all probability, quite correct It is to be remarked, however, that such findings apply only to preparations on the market prior to 1900, and there is no evidence to show that the synthetic preparations of the present day are not chemically pure There is in fact, evidence to support the view that they are pure (Waddell[1]) On this point we must remember that there is reason to believe that sodium paracreosotinate in small amounts is not toxic to man,[1 15 16] and this is the chief impurity blamed for the alleged inferior worth of the artificial salicylate

There is experimental evidence from three sources only First is that from Charteris and Charteris and Maclennan This ultimately showed that it is commercially possible to purify the artificial salicylic acid so completely as to yield a product, physically, chemically and pharmacologically identical with the "natural" And the author of this work advises the use of the artificial salicylic acid thus purified The second experimental work is that of Stockvis This, we have seen, means, if it means anything, that the artificial and "natural" salicylates have the same qualitative actions, but that the "natural" is *milder*, though no less fatal The last experimental work, that of Waddell, gives very strong evidence that the *cheapest procurable artificial salicylates* of the present day are in no way different pharmacologically from the costly "natural"

In the period of thirty-eight years during which time the artificial salicylates have been in use in medicine, there are to be found, in the entire realm of accessible literature, less than twenty-five communications dealing, even casually, with the relative advantages of the artificial and the "natural" salicylates In all these years many thousands of patients have been treated with large doses of the artificial salicylates and many of the ablest clinicians and the most acute observers in England, America and on the Continent have watched the results of such treatment Yet there are a scant fifteen who have been led to report these preparations as being more harmful than any other form of salicylate administered under similar conditions, and in similar amounts The rest have probably rightly attributed such ill effects as mental excitement, delirium, nausea, vomiting, tinnitus and the like to an excessive amount of the drug or to an idiosyncrasy on the part of the patient, or perhaps to both

We have to remember, also, that nearly all of the reports of the deleterious actions of the synthetic salicylates were made well over ten years ago, and that it is possible that at that time certain samples of these products were badly contaminated

At the present time the idea of the superiority of the "natural" salicylates is sedulously fostered by certain manufacturers, rather than by the experiences of the medical profession In the "literature" and advertisements of one of these, Charteris is quoted as one of the powerful advocates of the "natural" salicylates I would suggest that, in the future, mention should be made of his second and third papers, rather than of the first only

In conclusion, let me say that I have presented all of the evidence from the literature which I can unearth I have tried to make the excerpts and quotations in such a way as to present the opinions of the several authors with neither omissions nor alterations, such as might in the least alter the mea [illegible] each wished to convey Lastly, I have broug [illegible] objections to [illegible] dence on either si [illegible] me in the rea [illegible] of this one

---

25 Lambert The Use of Salicylates in Rheumatism The Journal A. M. A Sept 9, 1911 p 898

26 Italics mine.

From the material at hand there seem to be but two logical conclusions

1 The evidence in favor of the "natural" salicylates rather than the artificial is extremely slight, or what amounts to the same thing, the evidence against the artificial salicylates is even less

2 In nearly forty years of use by physicians all over the world, the artificial salicylates have been found quite as effective as the "natural" and no more liable to produce unfavorable actions under similar conditions than are these vastly more expensive "natural" products

414 East Twenty Sixth Street

A METHOD OF CONTINUOUS DILATATION OF EXTENSIVE URETHRAL STRICTURE

JOSEPH RILUS EASTMAN M D
Clinical Professor of Surgery Indiana University School of Medicine
INDIANAPOLIS

Three decades ago the followers of Otis, who were very numerous, cut every stricture of the anterior urethra To-day strictures of the pars anterior are rarely cut This is owing to the teachings of Oberlaender, Wossidlo, Valentine and Kohlmann, and to the consequent increase of knowledge and more careful study of the dilatation treatment It took years to establish the principle that sounds and dilators are not used to stretch strictures Such an instrument in the urethra exerts a dynamic influence According to Oberlaender, it induces retrograde metamorphosis, a reconversion of the fibrillary tissues into the original small-celled deposit, permitting absorption It has been intimated that the cells of the infiltrate are rendered soluble or diffusible or absorbable by peptonization, and again that absorption is favored by a teasing apart of cells, as in the Bier method of inducing artificial hyperemia Whatever theory may finally explain the phenomenon it may be fairly stated that pressure absorption of urethral inflammatory infiltrations, soft and hard is an accredited and authentic observation

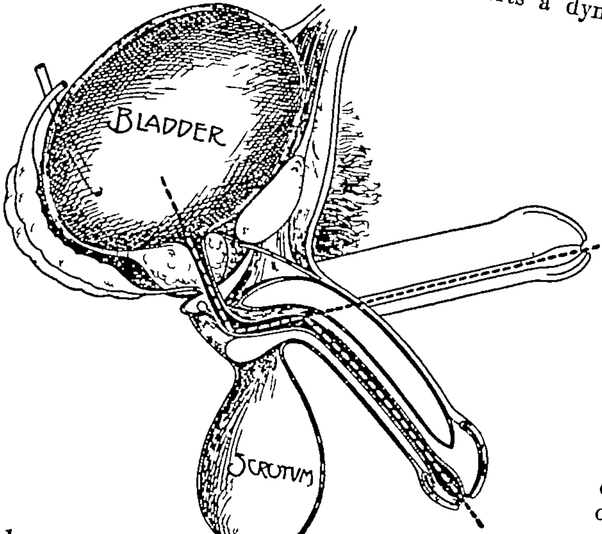

Fig 1—Curves at membranous portion of urethra and penoscrotal junction (after Gray) In erection only one decided curve is presen

After perineal section for strictures that narrow both the anterior and posterior divisions of the urethral canal, it has been my practice to drain the bladder by the natural route leaving a large soft rubber catheter in the urethra This plan has some advantages The period of convalescence is shortened, since the perineal wound closes more promptly if the urine be drained through the catheter The urinary salts which irritate the mucosa and favor stricture formation (Keyes) are not permitted to touch the urethra The caliber of the urethra is maintained or even increased, and the subsequent passage of instruments is rendered easy Much of the tedious work of after-treatment, such as sounding, becomes unnecessary or is decidedly lessened Soft and hard infiltrations of the pars anterior are removed by the pressure absorption induced by the presence of the catheter

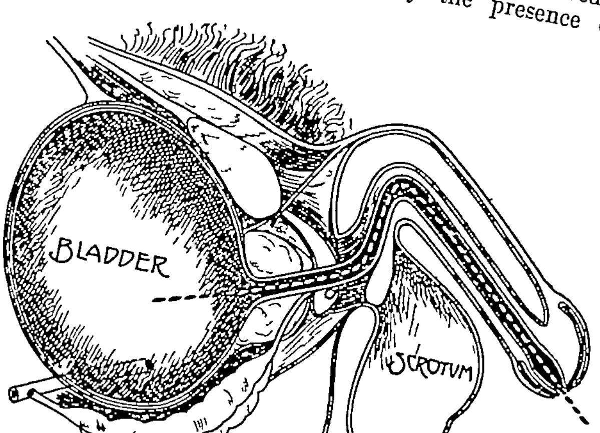

Fig 2—Sharp penoscrotal angle The normal angle is shown as it is exaggerated by depression of the outer end of the catheter into urinal

If a perineal drain alone be used, there is, of course, no continuous dilatation of the anterior urethra

There is, however, one defensible objection to the use of the dilating catheter if employed as described above Lying in the urethra and extending from the bladder to the external meatus it usually becomes sharply curved or angulated in the pars membranacea and at the penoscrotal juncture The pressure induced by the sharply flexed catheter at the penoscrotal angle has led to abscess formation or extensive inflammatory reaction often enough to suggest the need of a departure from the plan of using the same catheter for drainage and dilatation, and of employing instead two large elastic soft rubber catheters, one as a perineal drain, the other for dilatation of the pars anterior

It has been observed by those who are accustomed to drain the bladder through the urethra for certain conditions that a small soft thin-walled rubber catheter has less tendency to cause abscess than a large rubber tube with thicker walls The former, however, is of much less value as a dilator, and is more difficult to retain in position If the outer end of the catheter be drawn up over the abdomen and connected with a urinal at the side of the bed, one curve is made of the urethral canal, and the danger of abscess lessened It is not easy, however, thus to hold a catheter in place because of unavoidable traction

From Figure 1, it will be seen that if the external meatus be not depressed as it usually is in catheter drainage through the urethra, there need be no sharp angulation at the penoscrotal juncture If the penile portion of the urethra be elevated the entire pars anterior becomes quite straight

In order to provide simultaneous dilatation of the pars anterior and at the same time prevent angulation at the penoscrotal attachment, or bulbomembranous junction, one catheter is employed as a dilator of the posterior urethra and as a perineal drain The other short rubber tube is placed in the anterior canal The short catheter is passed from the meatus along the anterior urethra, which under anesthesia has been fully dilated, and is secured to the draining catheter by a chromic catgut loop at the opening in the membranous urethra If the danger of abscess be thus removed, the catheters may lie in the relative position indicated for two or three weeks, or longer if required, until the normal urethral caliber is permanently reestablished Ordinarily, catheters of 26 French are large enough, for the reason that after such an instrument has exerted its influence in the canal for two or three weeks the urethral caliber will be found to be several sizes larger (Charrières scale) than that of the catheter

The mechanical urethritis produced by a rubber catheter is, as a rule, unattended by symptoms other than discharge of mucopus from the meatus, which discharge subsides almost immediately on withdrawal of the catheter Such inflammations may be minimized by irrigation of the urethra before introduction of the catheter and subsequent irrigation, if practicable (it usually is practicable), between the urethral mucosa and the catheter Perhaps one patient in fifty cannot bear the retention catheter, owing to vesical spasm or chill, but even in these cases an opiate on the one hand or quinin on the other may make protracted retention possible

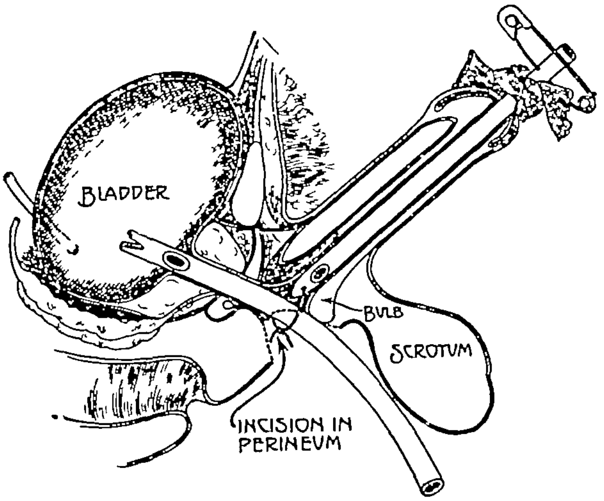

Fig 3—Author's method of draining bladder by large rubber catheter and passing second dilating catheter through anterior urethra to opening in membranous urethra where it is secured to first by a catgut loop The anterior urethra conforms itself to the catheter without angulation The penoscrotal urethral angle is temporarily obliterated Pressure here is relieved and inflammatory induration or abscess does not appear

In my cases there has been very little complaint of urethral pain, and the discharge was never annoying, usually just enough secretion of tough fibrinomucopurulent character accumulating during twenty-four hours to form a ring on the catheter at the meatus The decidedly benign urethritis became less active after the catheter had been in position for a few days In two cases the catheter was retained without changing for two months, and in these during the latter weeks, the discharge became practically *nil*

The urethral mucosa develops a tolerance for the instrument after a few days

In a few of my cases, during the first few days potassium permanganate in hot, weak solution was injected between the catheter and the mucosa, but even when this measure was omitted the urethritis was slight

The catheters used were of soft rubber, with two eyes Large sizes were chosen for the reason that such catheters as completely fill the lumen of the urethra occasion less frictional irritation than smaller ones, which readily bend sharply, or angulate, or slide and twist in the canal The presence of the large catheter in the bladder neck relieves irritability in this region Severe muscle spasm or tenesmus rarely occurs during its use

In order that during erection the outer end of the short catheter may not be drawn in through the meatus, it is secured by a safety-pin with a gauze ring to serve as a buffer

331 North Delaware Street

FAT EMBOLISM FROM A CHRONIC OSTEOMYELITIS

MERTON FIELD, M D
CANBY, MINN

The literature on "fat embolism" is remarkable because of its brevity and lack of detail Keen[1] gives a brief historical sketch of the subject, as do also LaConte and Stewart[2] In my study of the literature, however, I find no mention of fat embolism coming from a chronic bone disease with no apparent trauma Having had a case of the kind I feel it of sufficient importance to be reported

History—Miss H., aged 19, had typhoid fever at the age of 10 Since then the distal end of the femur had been the seat of a chronic inflammation with a discharging sinus In the fall of 1910 she was operated on The sinus healed and gave no further trouble until March, 1911

Present Illness—March 12, 1911, on her way to Rochester, Minn, the patient stopped off at Canby, Minn, apparently as well as when she left her home It should be noted that in addition to her railroad journey of 100 miles she had ridden fourteen miles over rough roads to the railroad station I was consulted regarding an embarrassment in her breathing Her condition was in no way serious, and my impression was that it was a simple bronchitis caused perhaps, by a slight cold, although there was no evidence of such a condition The pulse was 90, the temperature normal and the respirations were slightly *rough and bronchial*

March 13 the patient was more comfortable The bowels and kidneys were active The urine was free from albumin and microscopically was free from casts or other matter For the next four days her condition was practically unchanged except for returning paroxysms of dyspnea March 18 the patient had a hard night Breathing was difficult and cyanosis marked, but temperature was normal The bowels and kidneys were active

Treatment and Course—March 19 the patient had another hard night Some relief was obtained by the use of atropin, morphin and strychnin hypodermically The pulse range for the day was from 93 to 140, the temperature was normal while the respirations were from twenty four to twenty eight At 1 p m the chart read "cyanotic, heart action weak, respirations short, wheezy, painless" There was retention of urine, of which 14 ounces were taken by catheter during the day The patient was in great distress and was vomiting Epinephrin (adrenalin chlorid, P, D & Co) hypodermically gave some relief At 8 45 p m there was a "terrible struggle for breath" At 11 25 p m the chart graphically described the patient's condition as 'rigid, cyanotic pulseless, and comatose for forty minutes" Dr Henrik Tillish was called in consultation To him the case appeared as one of the extreme types of asthma

---

[1] Keen's Surgery i, 462
[2] LaConte and Stewart American Practice of Surgery vii 198

Examination of Urine—On further study of the case I was impressed by the similarity of her condition to that which I once saw in an embolism from a compound fracture of the tibia Thinking that I might now be dealing with such a condition I took a sample of urine and examined it for the presence of fat This urine was taken by catheter while the patient was still in a semicoma, but no fat was found even after a long search with the microscope March 20 the patient's condition was improved over that of the previous day She was vomiting, and had a severe headache and nervous twitchings of the extremities She was also very weak and had retention of urine A sample taken at 7 30 p m was examined chemically and microscopically Sugar and albumin were not found but fat globules of all sizes were abundant The characteristic globules of fat were unmistakable March 21 the patient was nervous but passed urine voluntarily Fat was still present microscopically

March 22 the patient's condition was again critical. There were cyanosis, vomiting, violent headache and nervous twitching of the extremities Breathing was very difficult, the heart was weak and the pulse irregular, varying from 78 to 148, with a variation in temperature from 98 6 to 100 F, and respiration from eighteen to forty six Dr C J Holman of Mankato was called in consultation It was agreed that the diagnosis could be made only by the presence or absence of fat in the urine Urine taken March 22, during the attack, was fat free This was examined by Dr H D Vahn, pathologist of the Immanuel Hospital laboratory, Mankato, and myself I cannot give Dr Vahn's method of examination, have reason to believe that it can be relied on March 23 patient was easier I again made a microscopic examination of the urine and found fat globules in abundance Wishing for further evidence I again sent a sample of the urine to Dr Vahn for examination He confirmed my report March 24 to 30 improvement continued but with repeated mild attacks of dyspnea The mental condition was improved and the convalescence though slow, was encouraging

I have been unable to follow closely the recent history of the patient She went west thinking that a change of climate would be of benefit In this she has been disappointed and has been in failing health since The last I heard of her was to the effect that she was again in the hospital in very poor health

The diagnosis of this case depended on the presence of fat in the urine, and its intermittency Keen[3] tells us that in "every suspected case of fat embolism the urine should be examined for fat While in exceptional cases oil drops may not be detected in the urine, their presence confirms the diagnosis" LaConte and Stewart[4] say that "lipuria may, of course, be encountered in any condition mentioned above in which excessive lipemia is found Scriba was able to demonstrate the presence of fat in the urine of all his patients with fracture He found, however, that in fat embolism the lipuria was intermittent"

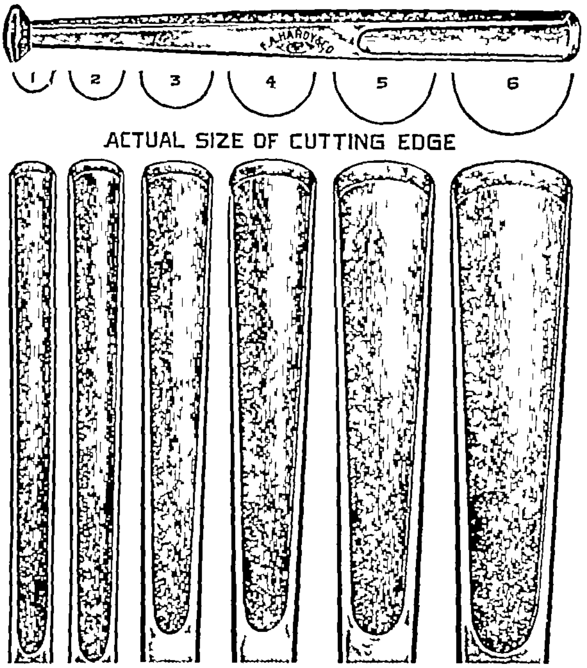
It is also to be noted that in the case which I have reported, fat was found only after the severe attack of dyspnea and cerebral disturbance Extreme care was taken that the samples of urine were not contaminated with fat from outside sources and the results as given cannot be questioned

---

NEW MASTOID CHISELS

Frank Allport, M D, Chicago

There are various mastoid chisels in use some being acutely rounded at the end some being square, others having concave convex bodies and still others being flat All have their advantages and their disadvantages Those with markedly rounded cutting edges allow the apex to sink into the bone before the sides, and thus necessitate uncertain chiseling, while the square edged chisels, with pointed corners, are dangerous, as injury to the nerves, sinus, brain, etc, is liable to be caused by the sharp angles of the lateral edges To avoid such difficulties and to possess a chisel combining the good and none of the bad qualities of the instruments in general use, I have had made, in six different sizes, a set of chisels which are concave convex, bevel sharpened on the front, very gently rounded on the back and slightly rounded on the edge with the corners turned forward so as to inflict no injury For safety, sureness, accuracy and ease of manipulation, I have found them more satisfactory than any other chisels I have used



New mastoid chisels

7 West Madison Street

New and Nonofficial Remedies

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS ARE ASKED FOR TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK "NEW AND NONOFFICIAL REMEDIES"

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT, SO FAR AS KNOWN, IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL

W A. PUCKNER, SECRETARY

GLYCOTAURO—Bile Salts, H W & Co—Glycotauro is concentrated ox bile, freed from bile pigments, each 1 Gm representing approximately 10 Cc of fresh ox bile

Glycotauro is prepared by evaporating ox bile in presence of animal charcoal extracting the residue with purified methyl alcohol filtering evaporating the filtrate and mixing the residue with glycerin

Glycotauro is a soft, semi-solid mass of light brown color bile like odor and slightly bitterish taste It is easily soluble in water and alcohol. Its specific gravity is about 1 22

---

[3] Keen's Surgery i 406

[4] LaConte and Stewart American Practice of Surgery vii 201

Actions and Uses—See Bile Salts (N N R, 1912, p 44)

Manufactured by Hynson, Westcott & Co, Baltimore Md No U S patent or trademark.

Glycotauro Capsules, 5 grains—Each capsule contains glycotauro 0 3 Gm (5 grains)

Glycotauro Pills, 1 grain—Each pill contains glycotauro 0 06 Gm (1 grain)

MERCURIAL OINTMENT, IMPROVED, Mulford—An ointment containing 50 per cent of metallic mercury in an ointment base consisting of anhydrous wool fat, petrolatum and suet, aromatized

Mercurial ointment improved is a slate colored semi solid mass having a pleasant, aromatic odor

Actions and Uses—The same as Mercurial Ointment, U S P Mercurial ointment, improved, is devoid of the unpleasant odor of Mercurial Ointment, U S P, and is claimed to be more readily absorbed.

Dosage—The same as Mercurial Ointment, U S P

Manufactured by the H K. Mulford Co Philadelphia Not patented or trademarked

Capsules Mercurial Ointment, Improved Mulford 30 grains—Each capsule contains mercurial ointment improved Mulford 2 Gms (30 grains)

Capsules Mercurial Ointment Improved Mulford 60 grains—Each capsule contains mercurial ointment improved Mulford 4 Gms (60 grains)

Therapeutics

DISTURBANCES OF THE HEART

(Continued from page 1973)

CHRONIC DISEASE OF THE VALVES

The development of permanent injury to one or more valves of the heart may have been watched by the physician who cares for a patient with acute endocarditis Or it may have been noted early during the progress of arteriosclerosis or other conditions of hypertension On the other hand, many instances of valvular lesions may be happened on in a life-insurance examination, or are discovered by the physician making a general physical examination for an indefinable general disturbance or for local symptoms, without the patient ever having known that he had a damaged heart The previous history of such a patient will generally disclose the pathologic cause or the physical excuse

As soon as a valve has become injured, the heart muscle hypertrophies to force the blood through a narrowed orifice or to evacuate the blood coming into a compartment of the heart from two directions instead of one, as occurs in regurgitation or insufficiency of a valve The heart muscle becomes hypertrophied, like any other muscle which is compelled to do extra work Which part or parts of the heart will become most enlarged depends on the particular valvular lesion In some instances this enlargement is enormous, increasing a heart which normally weighs from 10 to 12 ounces to a weight of 20 or even 25 ounces, and extreme weights of from 40 to 50 ounces and even more are recorded

As long as the heart remains in this hypertrophied condition, which may be called normal hypertrophy since it is needed for the work that has to be done in overcoming the defect in the valve, there are no symptoms, the pulmonary and systemic circulation is sufficient, and the patient does not know that he is incapacitated Sooner or later, however, the nutrition of the heart, especially in atheromatous conditions, becomes impaired, and the lack of a proper blood-supply to the heart muscle causes myocardial disturbance, either a chronic myocarditis or fatty degeneration If there is no atheromatous condition of the coronary arteries, and arterial disease is not a cause of the valvular lesion, compensation may be broken by some sudden extra strain put on the heart, either muscular or by some acute sickness or a necessary anesthetic and operation From any of these causes the muscle again becomes impaired and the heart, especially the part which is the weakest and has the most work to do relatively to its strength, becomes dilated, compensation is broken and all of the various circulatory disturbances resulting from an insufficient heart strength develop

As long as compensation is complete, there is no medication and no physical treatment necessary for the damaged heart The patient, however, should be told of his disability, and restrictions in his habits and life should be urged on him The most important are that all strenuous physical exercise should be interdicted, competitive athletic work should be absolutely prohibited, prolonged muscular effort must never be attempted, whether running, rowing, wrestling, bicycle riding, carrying a heavy weight upstairs or overlifting in any form The patient should be taught that he should never rush upstairs, and that he should never run rapidly for a car or a train or for any other reason, he should not pump up a tire, or repeatedly attempt to crank a refractory engine, even the prolonged tension of steering a car for a long distance is inadvisable He should be told that after a large meal he is less capacitated for exertion than a man who has not a damaged heart It is better if he drinks no tea or coffee, it is much better if he absolutely refrains from tobacco and alcohol Prolonged mental worry, business frets and mental depression are all injurious to his heart Anything that seriously excites him, whether anger or a stimulating drug, is harmful Any disease that he may acquire, especially lung disturbances, as pneumonia or even a serious cough, requires that he take better care of himself and be more carefully treated and take more rest in bed than a patient who has not a damaged heart Anything that raises the blood-pressure is of course more serious for his heart than for a perfect heart, therefore the drinking of large amounts of liquid, even water, is inadvisable It simply means so much more work for the heart to do Such patients should rarely be given any drug that causes cardiac debility, and should never take one without advice This applies to all the coal-tar drugs

One other fact should be impressed on the individual with a valvular lesion and compensation, and that is that he has but little, if any, reserve circulatory power In other words, while he is in apparently perfect health, it takes little circulatory strain to push his heart to the point of danger or insufficiency As nothing keeps this reserve so good or increases it more than rest he should expect to have a restful day at least once a week, and a good rest of at least two or three weeks once or twice a year

A patient with these restrictions may live for years with a serious valvular defect and may die of some intercurrent disease that has nothing to do with the circulatory system

It is easily recognizable that as the majority of acute lesions of the valves occur in children, it is impossible to prevent them from taking more or less strenuous exercise, and this is probably the reason that we have so many serious broken [illegible] tions [illegible] youth or early adolescence

As referred to und [illegible]

The Propaganda for Reform

IN THIS DEPARTMENT APPEAR REPORTS OF THE COUNCIL ON PHARMACY AND CHEMISTRY AND OF THE ASSOCIATION LABORATORY TOGETHER WITH OTHER MATTER TENDING TO AID INTELLIGENT PRESCRIBING AND TO OPPOSE MEDICAL FRAUD ON THE PUBLIC AND ON THE PROFESSION

PERUNA ONCE MORE

"Dr" Hartman, who, to all intents and purposes, is the Peruna Company, evidently has a desire to "get back" at the American Medical Association in particular and at decent physicians in general for the damaging exposés he has received at their hands To do this, he has published a large advertisement during the last few weeks headed, "Dr Hartman Makes Public the Facts As to What Doctors Think of Peruna" In it, the Peruna company declares that it has received letters from "regular practicing physicians" who have offered to write testimonials for Peruna, providing they received pay for them "But," says Hartman virtuously, "I have always refused to pay for such a service" Then he goes on

> I recently received such a letter from Kentucky from a doctor who says he has been practicing medicine for a quarter of a century and is at present medical referee for this county president of the county medical board local surgeon of the C & O Railroad member of the state medical society and American Medical Association and all that He has used Peruna and offers to give me a very remarkable testimonial if I would pay him for doing so

"It was very gratifying," says Hartman, "to receive such a testimonial from a brother physician and quite a temptation to pay him a small sum and allow his letter to be published" But no, Hartman could not bring himself to do such a thing as to pay out money for a testimonial! He publishes most of the letter anyway, however, and it doubtless made just as good bait for "suckers" and was much cheaper Says Hartman

> In referring to the doctor s letter I do not consider that I am violating the ordinary courtesies and confidences of private correspondence I have not made use of his name or the town where he resides But I am perfectly willing to communicate the name and address by private correspondence if any one wishes me to do so

For the purpose of "calling" Hartman's bluff letters were written to him asking for the name and address of the Kentucky physician member of his state society and of the American Medical Association, who had offered to sell a testimonial for Peruna One of these letters was from a physician in Illinois another from a minister in Michigan and a third from a stenographer in Kentucky Each writer received a letter from Hartman stating that while he was 'always glad to show people letters and testimonials" he would want further information regarding the 'use you are proposing to make of this name and address" before he would be willing to send it He continues

> The fact that you are a physician [a Reverend] [a woman] leads me to believe that you are not intending any hostility either toward the doctor or myself

Presumably if he had received letters from a butcher, a baker or a candlestick maker, the fact" that the writer was a butcher, a baker etc would "lead Hartman to believe that he was 'not intending any hostility"

The minister wrote back to Hartman that he desired the name so that he might write to the physician in question and find out whether he really did recommend Peruna This brought another letter from Hartman stating that the Kentucky physician no longer was friendly to him but that he would enclose—and did enclose—a copy of the original letter which he received from the Kentucky doctor Here is a copy of the letter

> Frenchburg Ky Sept 27 1910
>
> The Peruna Medicine Co, Columbus Ohio
>
> *Gentlemen* —I write to ask you if a testimonial from a grateful patient would be of any particular value to you I have practiced medicine for a quarter of a century and have been afflicted with a subacute inflammatory condition of the post nasal space and of recent years he larynx had been involved in the catarrhal process Have also been for the last fifteen years addicted to the constant use of morphia Your medicine has entirely relieved me of both conditions after only a comparatively short time and to-day am the happiest man alive Medical men will hardly believe me when I tell them that your medicine cured me of the opium habit, but it is a fact nevertheless I had tried for fifteen years every known means and took treatment at several sanitariums as every one in this part of the country will know I am willing to make oath to the above statement and if you wish it and are willing to make it worth my while I will write you the testimonial that will be valuable to you as an advertisement. I do this with no mental reservation whatever believing as I firmly do that it cured me of the most damnable habit or disease to which humanity is liable
>
> My action in this matter may have a tendency to stagger my medical friends, lauding an irregular medicine but I have considered the matter carefully and prayerfully and I propose to stand by my honest conviction I am the medical referee for this county president of the county medical board local surgeon of the C & O R R Rothwell to Mt Sterling member state medical society and American Medical Association My action may and I have no doubt will cause some criticism
>
> I am also preparing an article to be read at our next meeting of our county society on catarrhal diseases of the pharynx My treatment for these troubles is the free and regular exhibition of your Peruna Will send you a copy of the article if you wish it If you wish to use it for the benefit of suffering humanity I will send you the testimonial with my photo There is no gallery here but I can got one by going to Mt Sterling Ky thirty miles from here I am satisfied this will redound to your benefit in a financial way but the best of all if it will be the means of saving even one poor soul from a living hell I will be satisfied I am treating now seven cases of opium habit and my principal treatment is your preparation
>
> I am a graduate of the University of Louisville Ky class of 87 and have taken the postgraduate courses at New York the last five years
>
> Yours very truly and gratefully
>
> JOHN L BROWN M D

In the Peruna advertisement, which appeared in October, 1912, Hartman states, regarding the letter just given,

> I recently received such a letter

In each of his letters to those that wrote him asking for the name and address of the physician, Hartman said

> I have the doctor s letter in my office recently received

Now note the date of the letter "recently received" from John L. Brown—September, 1910! In other words, the letter had been in cold storage for more than two years! So much for Hartman's accuracy Now just a word regarding John L Brown Brown declares in his letter that he is, among other things (1) medical referee for his county, (2) a member of the Kentucky State Medical Association, and (3) a member of the American Medical Association The secretary of the Kentucky State Medical Association declares that Brown was never medical referee for his county nor was he a member of the Kentucky State Medical Association For the rest, we may say that Dr John L Brown, self admitted morphin addict, who was willing after he had "considered the matter carefully and prayerfully," to give a testimonial for Peruna—providing Hartman "came across"—is not, and never has been, a member of the American Medical Association

Correspondence

The Value of Tetanus Antitoxin

To the Editor —While the value of tetanus antitoxin in the prophylaxis of tetanus is generally accepted, its efficacy in combating the disease after symptoms have appeared is not so clearly demonstrated Some men are firmly convinced that tetanus antitoxin in large doses has been the means of saving patients suffering from tetanus, others are as certain that it does no good Most of the texts on medicine and surgery suggest antitoxin in the curative treatment of tetanus, but add that little benefit is to be expected from its use

It is scarcely necessary to refer to the importance in the prognosis of tetanus of the site and extent of the initial wound, of the incubation period, of the adequacy of local surgical treatment and of the various symptomatic remedies employed In those cases in which serum has been administered, the method of introducing the antitoxin whether subcutaneous, intramuscular intravenous, intraneural, subdural, etc, must be considered.

Since the outcome of this disease depends on so many variable factors quite independent of specific treatment, the study of the individual case or of a small group of cases affords practically no safe data for generalization Similarly, conclusions drawn from a collection of case reports from the literature will be misleading, for favorable cases are more often reported than unfavorable cases

The current view of the curative value of tetanus antitoxin is derived, of course, in part from animal experiment and in part from the larger collections of case reports One of the most extensive and frequently quoted of these reports is that of Anders and Morgan,[1] which included 949 cases from the literature (1850 1904) and 252 original cases obtained by correspondence with clinicians in this country From their study Anders and Morgan concluded that "the present status of the serum question leaves no room for doubting that when given during well-developed cases of tetanus, antitoxin has no appreciable beneficial effect, neither reduction of mortality nor hastening of recovery resulting therefrom "

Thus out of 140 patients treated without serum, 77 per cent died, of 112 patients treated with serum 63 4 per cent died A somewhat more detailed study of these statistics shows, however, that of the patients who were treated with serum, but who died, many received only small doses of serum (for instance, 20 or 40 c.c.) In the accompanying tabulation the cases are classified with respect to the amount of serum used

	Number of Cases	Mortality Per Cent
Total cases	252	71
Without serum	140	77
With serum—all cases	112	63 4
Serum in small amounts	71	70 4
Serum in large amounts (100 c.c. or more)	41	51

The incubation periods of the fatal and non fatal cases showed practically the same relation in this classification Conclusions drawn from such tabulations are of course open to criticism from several points, but these figures suggest that large doses may have a demonstrable beneficial action Moreover, most of the American statistics, including those of Anders and Morgan just quoted, were based on cases treated prior to 1905 In 1907 an American standard unit for tetanus antitoxin was promulgated by the Public Health Service[2] and since 1907 commercial tetanus antitoxin has been much more uniform in quality and of higher antitoxic value Thus in seven American serums examined by Rosenau and Anderson[4] prior to 1907, the antitoxic content varied from 77 to 769 units per cubic centimeter In five foreign serums the antitoxic content varied from 40 to 83 3 units per cubic centimeter

During the past five years, therefore, tetanus in the United States has been treated with serum of a more uniform value and it would seem desirable to ascertain by a compilation of results what may be hoped for in the treatment of tetanus with antitoxin of uniform grade

We recognize of course that much of the experimental evidence indicates that after tetanus toxin is fixed in nervous tissue, antitoxin is of little service in saving the life of an animal On the other hand, in a case of tetanus in man, it often is not possible to determine how far this intoxication of nervous tissue has progressed, by reference either to the incubation period, or to clinical symptoms Nor is it always possible to be certain that local surgical treatment has completely eradicated the source of the toxin That a limited intoxication is not necessarily fatal is proved by recovery in apparently hopeless cases

As the matter now stands, the general practitioner, when called on to treat a case of tetanus, refers to his texts, finds but scant encouragement for vigorous serum treatment and at best is likely to give but two or three doses of serum If the accumulated clinical results show that antitoxin adds nothing to the chances of recovery of the patient, the present pessimistic view is justified and we must continue to depend on symptomatic and local treatment, but if serum in large doses will save an occasional patient, it should be used as a routine with the other approved symptomatic remedies

A consideration of the facts given above suggests the reopening of the discussion of a rather old subject, regarded by many as settled, in the hope that the collected experience of the past five years may help to determine from clinical results the value of antitoxin to tetanus sufferers

Those who have treated cases of tetanus since 1906, either with serum or by other methods, are requested to communicate with me in care of the Memorial Institute for Infectious Diseases Blanks will be forwarded for recording the necessary data, and due credit will be given in the compilation to be made later

ERNEST E IRONS,

The Tariff on Surgical Instruments

To the Editor —At this time, when tariff revision promises to be the order of the day, would it not be a good idea for the American Medical Association to endeavor to secure the abolition, or at least reduction, of the heavy duty paid by the medical profession of the United States on surgical instruments? It is currently believed that this duty benefits merely two or three importing firms, and perhaps a similar number of instrument manufacturers in America, and this at the expense of the entire medical profession of this country I have understood although I cannot speak authoritatively in this matter, that there are one or two instrument importing houses in New York which import German surgical instruments in the rough—that is, not nickel plated—on which a duty of 5 per cent is charged, nickel plate these instruments and then stick on the 40 per cent. duty Furthermore, the manufacture of surgical instruments in America seems never to have attained to large proportions, and promises not to so do for many years, yet the medical profession must continue to pay this 40 per cent duty on instruments which half the time they use in performing charity operations Pertinent to this matter of American instrument manufacture, I recall that a year or so ago I wrote to a Chicago instrument house inquiring why they charged me $2 more for a certain kind of tonsil snare than did a New York instrument house The reply came that their instruments were hand forged, and not the cheap German imported instruments, but they had overlooked the important fact that both instruments bore the well known trademark of Fischer of Jena! So much for the home grown product Why should the medical profession of America, with all its political strength, submit to this tariff imposition?

RICHMOND MCKINNEY, Memphis, Tenn

Immunity in Pneumococcus Infections

To the Editor —In THE JOURNAL, Oct 12, 1912, there appeared an article by Dr J O Hirschfelder, of San Francisco, on active and passive pneumococcus immunity This article is a valuable communication and Dr Hirschfelder is to be congratulated on the resourcefulness and ingenuity of his experiments and deductions His work is of unusual interest to me since it parallels certain observations of my own, which have been in progress since November 1910 My own work has been concerned chiefly with studies of a group of organisms which has the common characters of autolysis and enzyme production, namely, the pneumococcus, the gonococcus and the meningococcus, and to a lesser degree the staphylococcus Of these organisms, the pneumococcus alone lends itself to animal experimentation, and the work of Rosenow and others has done much to clear up the nature of the autolytic processes and the chemical and biologic characters of the autolysates

The enzymes of this group of organisms, of which the pneumococcus may be regarded as the type, are proteolytic and appear to operate like enzymes of the tryptic variety, i e, best in slightly alkaline mediums It has been shown by Dick that at the time of crisis in pneumonia the blood shows the presence of a proteolytic enzyme, especially in those cases which go on to recovery, and the inference is drawn that this enzyme is the product of pneumococcus activity

My own observation has led me to believe that this contention is true Using the highly susceptible rabbit, I have been studying the effects of immunity conferred by inoculations of infected animals with pancreatin solutions alone, with pancreatic extracts of pneumococci, and with like extracts of pneumococci and staphylococci So far as these experiments have gone, the indications point to the following conclusions first, that pancreatin solutions alone are capable of producing immunity in infected and non infected rabbits, second, that filtered pancreatic extracts of pneumococci, and of pneumococci and staphylococci also, show immunizing and curative powers, third, that all three of these agents are capable of modifying favorably the course of pneumococcus infections in man

It is my intention shortly to report the experiments and data leading to the above conclusions concerning pneumococcus infection, and the no less important data and conclusions in regard to the nature and therapeutics of gonococcus infection

Carl C Warden, Los Angeles, Cal

Queries and Minor Notes

Anonymous Communications will not be noticed Every letter must contain the writer s name and address but these will be omitted on request

IRID FLORENT AND PULV MAYORANAE

To the Editor —In an abstract of an article by A Lorand on The Relief of Headaches by Inducing Copious Secretion from the Nose (The Journal Nov 16 1912 p 1834) two suggestions as to prescriptions are made I am unable to find two of the articles required in my local druggist s stock nor can I find them described in Dorland s dictionary or any materia medica at hand I refer to the pulv mayoranae and the irid. florent. both of which occur in the second prescription Please tell me what these items are and where they can be obtained I do not recognize them under this name

P T F

Answer —"Irid florent" is evidently the genitive of "iris florentina"—Florentine iris, or orris root "Pulv mayoranae" evidently refers to powdered marjoram leaves, which are obtained from *Majorana hortensis*, a plant somewhat similar to sage and used largely for culinary purposes The German names for marjoram are *Wurstkraut* (sausage herb), *Majoran* and *Matran* Marjoram leaves are found in many drug stores as well as in some groceries that cater to German trade If marjoram is not available, sage or some similar herb would probably answer the purpose

MEANING OF THE WASSERMANN REACTION

To the Editor —Please inform me just what a positive Wassermann test of the blood signifies when performed by a competent laboratory worker Does it mean that the patient is at the time of the test suffering from active syphilis and that he is in need of further treatment—treatment until the test becomes negative or does it merely mean that the patient has at some near or remote period in his past life had syphilis? Is a positive Wassermann test of the blood with no other discoverable evidence of syphilis an indication for active treatment? My understanding has been that a positive Wassermann test of the blood merely signifies syphilitic infection and that it is only temporarily influenced by treatment that it frequently becomes negative during the course of active treatment, but invariably becomes positive again soon after treatment is discontinued I would be glad to have an authoritative statement of the significance of a positive Wassermann test of the blood serum

Heber Butts Canacao P I

Answer.—According to the present consensus of opinion a Wassermann reaction found positive on repeated examinations by competent laboratory workers signifies that the individual has been infected at one period of his life with the *Spirochaeta pallida* and that he still harbors active foci of the syphilitic agent If this infection as in the great majority of cases has led to the clinical manifestations which we call syphilis, or if these manifestations have been absent (latent syphilis), the positive Wassermann test means that there are still syphilitic products and producers present and that immediate specific treatment is therefore called for It is of course erroneous to conclude that cases which show only slight clinical symptoms may be treated lightly The history of tabetics and paralytics shows only too often "light" cases of syphilis in which there are only slight secondary symptoms The treatment of patients who give a positive Wassermann reaction but who show no clinical manifestations of syphilis should be thorough and should include one course of inunctions each year and potassium iodid for several months each year until the Wassermann test, taken at intervals of six months, has remained negative for two years

As in other conditions antibodies may be present at a time when a disease has been cured, it is possible that a Wassermann test may be positive after treatment, though the patient is actually cured of his syphilis This positive Wassermann must after a certain time become negative spontaneously There is no evidence that antibodies may be present in high concentration years after an infection unless the infective agent is still harbored by the host The fact that the Wassermann test becomes positive after it has been negative for some time proves only that the treatment has been insufficient in its mode, in its duration, or in both

PREPARATION OF AUTOGENOUS VACCINES

To the Editor —Please tell me of a publication on the preparation of autogenous vaccines

E C Stevenson M D Dixon Ill

Answer —We find no book devoted to the preparation of autogenous vaccines, though chapters on this subject are found in several works The directions usually given for the preparation of autogenous vaccines are, in substance, as follows

Autogenous vaccines are mixtures of the organism, derived from the individual patient, which appears to have an etiologic relation to the disease The first step is therefore to determine the bacterial cause of the disease and obtain the organism in pure culture The organism must be as virulent as possible, and for this reason the isolation of the bacterium from the morbid material must be effected as rapidly as possible in as few generations as is consistent with obtaining it in a state of purity The culture of the vaccines to be used must be prepared under the most favorable conditions When the organism responsible for the given infection has been isolated from the lesion existing in the patient, it is planted on a suitable medium in a Roux or similar bottle to form mass cultures, and is incubated under optimum conditions for such a period of time as experience shows is calculated to yield the maximum number of vigorous living bacteria Salt solution is then added to the growth, a few cubic centimeters being usually sufficient, and the culture scraped off into the salt solution with a sterile glass rod or platinum loop The number of bacteria per cubic centimeter is then estimated by mixing equal volumes of defibrinated blood and bacterial suspension and then diluting about five times and smearing on a slide This is stained with a Romanowski stain and the number of red corpuscles and also that of the bacteria ascertained

Since the number of corpuscles in normal human blood is about 5,000,000 per cubic millimeter, by a comparison of the number of bacteria with the number of corpuscles in the field examined the number of bacteria per cubic centimeter can readily be estimated Having determined the numerical strength of the vaccine, a sufficient quantity of salt solution is added to the emulsion to reduce the numbers in each cubic centimeter to 1 000 or 100,000 000, or to whatever quantity is selected as the standard, and the mixture is well shaken The tube is then suspended for a period of thirty minutes in a water bath kept at a temperature corresponding with the thermal death point of the bacterium employed for the vaccine, for example, from 59 to 60 C (138 2 to 140 F) for *Staphylococcus aureus* After removal from the water bath loopfuls of the emulsion are sown on suitable mediums and incubated in order to determine the sterility of the vaccine Finally a small quantity of some antiseptic, such as 0 5 per cent phenol, or 0.25 per cent trikresol is added to the vaccine, which is then put up in small bulbs or rubber capped bottles for use

THE INCOMPATIBILITIES OF HEXAMETHYLENAMIN

To the Editor —I have been an interested reader of the various discussions on hexamethylenamin that have appeared in The Journal during the last few years No one of the articles that I have read however has touched on the subject of its compatibility with other drugs Please give me some light on this subject.

W H Conner M D., Gilbert Minn.

Answer.—The incompatibility of hexamethylenamin with sodium acid phosphate, due to the acidity of this salt, was discussed in The Journal, Nov 2, 1912, p 1640 The fact that its solutions are decomposed by acids was discussed in The Journal, Nov 30, 1912, p 1989 Other incompatibles are tannic acid and mercuric chlorid, which precipitate hexamethylenamin.

LITERATURE ON PELLAGRA

To the Editor —Please refer me to articles and books on the signs and symptoms of pellagra which have been published since June 1911 H C ——— Miss

Answer —In this department, Sept 28, 1912, p 1205, appeared a list of Journal articles on the etiology, symptoms and treatment of pellagra The following list includes later Journal articles and books and articles that have appeared elsewhere

Wood Edward Jenner A Treatise on Pellagra Price $4 D Appleton & Co New York 1912
Roberts Stewart R Pellagra History Distribution Diagnosis Prognosis Treatment Etiology Price $2 50 C V Mosby St Louis 1912

Phenomena of Anaphylaxis in Pellagra Patients Inoculated with the Watery Extract of Spoiled Maize The Journal Oct 19 1912 p 1480

DIFFERENTIATION OF MEASLES AND GERMAN MEASLES

To the Editor —Considerable discussion has arisen here as to the etiologic differentiation of measles and German measles Please give me any information or literature Can a person with German measles infect a second person with measles?

J W Warren, M D Plymouth Mich

Answer.—So far as is at present known, German measles (rubella or rötheln) and measles (rubeola or morbilli) are distinct diseases Recent investigations have shown that it is possible to communicate measles to apes and monkeys and some important facts have been learned regarding the character of the virus but we do not know that any similar experiments have been made with the virus of German measles According to the prevailing opinion a person sick with German measles would not communicate any other disease than German measles He would not infect a second person so that the second person would develop genuine measles

DATE OF INTERNATIONAL MEDICAL CONGRESS

To the Editor —Some time ago I read in The Journal of the medical meeting to be held in London next August Since then I have seen nothing in regard to it. I should like to attend this meeting We are but twelve days now from London nearer than the physician in San Francisco

M S Stewart M D East Gate Seoul Korea

Answer —The Seventeenth International Medical Congress will be held in London, Aug 6 12, 1913 Information concerning the congress was given in The Journal, Feb 3, 1912, p 356, and July 27, 1912, p 285

PROLONGED ALKALINE TREATMENT OF HYPERCHLORHYDRIA

To the Editor —In The Journal (Nov 23 1912 p 1910) M T R. shows that he believes in sodium bicarbonate for hyperchlorhydria Please in your query column draw his attention to the following

℞ Magnesia calcined gr v
Bismuth subnitrate gr x

This was prescribed for me three years ago and its continued daily use has wrought no harm but unqualified happiness.

INFORMATION DESIRED ON HABITUAL SUBNORMAL TEMPERATURE

To the Editor —I am interested in habitual subnormal temperature I have a few patients under observation who show a daily range of temperature from 95 to 98 degrees All these patients while in a state of low vitality are attending to their usual employment I wish to tabulate and compare the symptoms connected with this condition and therefore ask for information with regard to such cases

N R. Gordon M D Springfield, Ill

PREGNANCY AFTER OOPHORECTOMY

To the Editor —I am interested in the subject of pregnancy after oophorectomy and would appreciate certain information from those who have had cases of this kind The information desired involves the question of the relief of sterility following this operation the character of the labor where pregnancy has occurred the indications for removal of the ovary, the pathologic condition any other operations done at the same time the character of the menstrual periods subsequent to the operation and the date of birth and sex of subsequent children A blank form will be forwarded in reply to a post-card request

GOOD HEALTH A BUSINESS PROPOSITION

Reference has previously been made to the excellent work being done in the education of the public by some of our large life insurance companies One of the most conspicuous examples is the Equitable Life Assurance Society, which has established a department of conservation, devoted to the prevention of disease and the prolongation of life among its policy holders It also issues a magazine entitled *The Human Factor* to its policy holders In a recent issue of this magazine appear some striking statements from an address by Mr E E Rittenhouse[1] the conservation commissioner of the society, before the International Conservation Congress, held at Indianapolis, Oct 2, 1912 which are worth quoting not only for the facts themselves but for the impressive way in which they are put Mr Rittenhouse said

"Our birth rate is declining Over 200,000 infants under age 5 die annually from preventable disease

'Of the 20 000 000 school children in this country not less than 75 per cent need attention for physical defects which are prejudicial to health

'The alcohol and drug habits are constantly adding to the degenerate list and the death roll

The diseases of vice are spreading, and we lack the moral courage to openly war against them

"Insanity and idiocy are increasing at an alarming rate

Suicides now reach the enormous total of 15,000 annually

Over 9 000 murders are committed every year in the United States Only about 116 murderers are executed for these crimes Our homicide rate is appalling—about 100 per million population, against 13 in Canada, 9 in Great Britain, 15 in Italy

'The diseases of old age are reaching down into middle life and below Our vital organs are wearing out too soon We have had an increase of over 100 per cent in thirty years in the death rate from diseases of the heart, blood vessels and kidneys, including apoplexy These diseases claim over 350 000 Americans annually Sixty per cent of them are preventable or postponable if detected in time

Cancer destroys nearly 75 000 lives annually The loss from external cancer alone has increased 52 per cent. in ten years

'Pellagra a deadly plague, is increasing in the South, but it excites little or no public concern

'Over 135 000 lives are taken by pneumonia, chiefly as a result of weakened resistance from degenerative disease

'Over 150,000 die annually from the preventable plague, tuberculosis Nearly a million tuberculous victims are constantly spreading the malady to the well, with virtually no official supervision or restraint

"Over 25,000 are killed and 300 000 attacked annually by the preventable filth disease typhoid fever Other germ diseases carry off more people than tuberculosis and typhoid combined

'Over 90 000 Americans are killed annually by accidents and other violence, and the loss is steadily increasing

"Over 1,500 000 people are constantly ill from preventable disease Over 6,000,000 people will die from preventable cause during the next ten years at the present loss rate

'The sum of $1,500 000 000 is a low estimate of the annual economic loss from preventable deaths

---

[1] Ritten [illegible] E. [illegible] ab tr., The [illegible]

"Our cities spend six and a half times as much to prevent fire waste as they do to prevent life waste, although the money loss from life waste is six times greater

"These are the conditions we are asking our people to correct Is there anything unreasonable in this request?"

By way of contrast to the somber picture given of conditions in this country, are the striking statements made in the first article in the number, under the title, "Our Life Saving Triumph of Panama," in which the work of the Sanitary Department of the Canal Zone for the last seven years is summarized

"Col William C Gorgas and his sanitary corps were charged with an extraordinary task. They undertook to drive from the pest ridden seaports, jungles and marshes of the Canal Zone the deadly fevers and other diseases which have scourged the Isthmus for 400 years Their success has challenged the admiration of the world

"They have transformed the world's greatest plague spot into a zone of salubrity and health They have given civilization most convincing proof that sanitarians can conserve human life even under the most appalling difficulties, *when they are given money and the authority to do it*

"Every American should know the story of what has been done From the statements and reports of Colonel Gorgas we learn the following

"Yellow fever has been banished—no case has occurred for six years

"The annual deaths per ten thousand employees from principal diseases has been reduced under American control (since 1904) as follows From dysentery 25 8 to 2 6 From tuberculosis 15 3 to 4 7 From malarial fevers 87 9 to 9 6 The annual malarial sick list has been reduced from 821 to 187 per thousand employees

'During the first nine years of French control the general death rate was 241 per thousand employees annually (That mosquitoes spread fevers was not then known)

'Under American control it has come down from 41 7 in 1906 to 11 0 in 1911

'The average number of employees under French control was 10,200, and the deaths were 22,189 During nearly the same length of time under American control, the average employed was 33,000 and the deaths were less than 5,000

"The general death rate in Panama, Colon and the Canal Zone has been reduced from 48.3 per thousand population in 1906 to 21 4 in 1911

'Could the American people ask any more convincing evidence that public health is purchasable?

'It is simply a matter of dollars and authority The cost of accomplishing these wonderful results on the Isthmus has been about $2 43 per person annually in the zone affected This is less than Key West spends annually for its fire department, where the death rate (22.5) is higher than it is in Panama

Are the lives of the white and black people of the Isthmus of any more value than the lives of the white and black people of the states?

"If Colonel Gorgas, under the most extraordinary difficulties, can conquer the diseases due chiefly to the mosquito and fly pest, why can it not be done in American cities where the obstacles to overcome are relatively trifling and the cost much less?

If we know how to change the deadly swamps and jungles of Panama into healthful abodes for man, what excuse have we for not applying the same knowledge to its full extent to American communities?

'It is difficult to realize that Panama, the former pest hole of the tropics, is now more healthful than a number of American seaport and river cities

'Compare the Panama death rate of 21 4 with that of Charleston, S C (1910 census) 29 7, Savannah 26 9, Mobile 23 0, Richmond 22 6, Key West 22.5, Memphis 21 4, New Orleans 21 3, Washington, D C, 19 6, and with the many other wealthy and prosperous American cities where the death rate is from 15 to 20 And there are scores of towns and cities in the United States with virtually no public health service

'Colonel Gorgas has emphasized the fact and placed it squarely before the American people, that the excessive death rate from preventable disease in our communities is nothing short of a communal crime"

One could hardly ask for a better demonstration of the fact, now being recognized, that good health is a purchasable commodity, and that sickness can be insured against and prevented if the public is willing to pay enough for safeguards

Georgia Board Upheld in Right to Refuse to Examine Graduates of Certain Colleges

The mandamus case brought by the Southern College of Medicine and Surgery against the Board of Medical Examiners of Georgia was called for trial in the superior court recently, but as no one was present for the college except the local attorneys, and as they refused to try the case, it was dismissed. This case was brought several months ago to compel the board to examine the graduates of this college The case was first heard by Judge Morris, was then taken to the supreme court by the college and later came back for trial before a jury, but, as stated above, the case was dismissed The board had refused to examine the graduates of the college on the ground that the college was not equipped properly, and was graduating its students before they had completed the course required by law It is supposed that the dismissal of the case will end the litigation over the matter

Louisiana Homeopathic November Report

Dr Edward Harper, secretary of the Homeopathic State Board of Medical Examiners of Louisiana, reports the written examination held at New Orleans, Nov 4 5, 1912 The number of subjects examined in was 10, total number of questions asked, 100, percentage required to pass, 75 Only one candidate, a graduate of the University of Michigan Homeopathic College, 1912, was examined and he passed with a grade of 82 5 per cent

Book Notices

Mind Cure and Other Essays By Philip Zenner A M M D Cloth Price $1 25 net Pp 160 Cincinnati Stewart & Kidd Company 1912

The subjects of mind cure, alcoholism, social diseases, the medical inspection of schools, the training of children, defectives and delinquents, and the betterment of the race through the science of eugenics are much in the minds of thoughtful men and women at present, and constitute problems in preventive medicine to which leading members of the profession are devoting their attention In this little volume Dr Zenner has treated these subjects in a sane, clear and forceful manner In the essay on mind cure he vigorously arraigns the quack and the nostrum vender with their vast and fraudulent pretensions, and calls attention to the shortcomings of osteopathy and the inadequacy and danger of the Christian Science cult and its pretensions in the cure of disease In the essays on the training of the child, the prevention of alcoholism and the social diseases he speaks clearly and practically on the need for education in these matters and the building of character in the young, in which lies the best hope of progress Eugenics and the problems of the defective and the delinquent are treated in the same enlightened, sensible manner, and for the handling of the latter he offers a practical method in the school of truancy which he was instrumental in establishing in his home city This is a sensible book on vital subjects and should interest every thoughtful person

The Medical Directory of New York New Jersey and Connecticut Volume XIV Cloth Price $2 50 Pp 821 New York Medical Society of the State of New York 17 W Forty Third Street 1912

The fourteenth volume of this directory is similar in style to those already issued and contains the names of 17,764 physicians of whom 13,696 are in the state of New York, 2,674 in New Jersey and 1,394 in Connecticut Of the 13,696 physicians credited to New York state, 5,159 are in Manhattan and the Bronx, 1,927 in Brooklyn, 213 in Queens and 66 in Richmond making a total for Greater New York of 7,365, leaving a balance of 6 331 as the medical population of the remainder of the state The directory contains only the names of registered physicians

The Vanishing Man A Detective Romance By R Austin Freeman Cloth Price, $1 25 net Pp 351 New York Dodd Mead & Co 1912

An excellent detective story of medicolegal character, the plot being based on the identification of bones The character sketching is good and the plot ingenious, while the love making between the physician narrator and the heroine suspected of murder is altogether satisfactory The story will be found not horrible or thrilling, but absorbing and entertaining

The Medical Record Visiting List or Physician's Diary for 1913 Leather Price $1 50 New York William Wood & Co

This admirable visiting list possesses the advantages of neatness and compactness It fits easily into the pocket and contains the tabloid information found ordinarily in publications of this character The blanks are in various forms for making conveniently the necessary records of visits and charges and for other data such as births, vaccinations, etc

Medicolegal

Inoculation With Venereal Disease Cruel Treatment of Wife

(Carbajal vs Fernandez (La) 58 So R 581)

The Supreme Court of Louisiana affirms here a judgment for the plaintiff in what it says was the suit of a young wife, chaste and pure, for a separation from bed and board on the ground of cruel treatment, consisting in having been inoculated with both gonorrhea and syphilis by her husband The defense was that the infection might have been communicated in other ways than by sexual commerce Possibly so, but the defendant (barely 20 or 21) *suffered from these diseases before* his marriage and was treated for them some six months before his marriage, and no later than three days before his marriage he consulted a physician to be informed whether in the opinion of the physician he had been cured, and marriage was safe The expert testimony showed that if contracted from commerce the diseases would first appear where they did in fact, manifest themselves As to whether the communication of a venereal disease constitutes cruel treatment, the brief of the defendant said The evidence unquestionably shows that plaintiff is afflicted with syphilis, that disgusting and terrible disease that carries in its wake untold physical and mental pain and anguish Defendant's earnest sympathy is extended to the plaintiff, whose suffering and humiliation have, unquestionably been great" Indeed all the courts agree on that point The only difference of opinion is as to whether it is necessary that the husband should have been aware of his condition In the present case the defendant had this knowledge or which is the same thing should under the circumstances have had it Wherefore, the judgment for the plaintiff is affirmed

Letting Drain Get Lost in Wound

(Evans vs Munro (R I) 83 Atl R 82)

The Supreme Court of Rhode Island approves of an allowance of $1,250 damages to the plaintiff on account of the defendant having permitted a drain to get lost and remain in the wound after he had performed an operation for the removal of a tumor from her breast The court says that there was no merit in any of the exceptions of the defendant There was no question but that the plaintiff was in the exercise of due care during the operation performed on her by the defendant, and thereafterward while under his care, and that it was through no fault of hers that the drain disappeared and was lost within the incision made by the defendant, and remained within the wound in her breast, which healed by first intention As such drains are not ordinarily permitted, in the exercise of good surgery, to remain within the body of a patient after a wound has so healed, proof of the fact that the drain in question was left by the defendant in the breast of the plaintiff imposed on him the burden of explaining that its presence there was not due to his negligence in the premises The damages awarded were not so large as to shock the conscience of the court, or to indicate that the verdict of the jury was actuated by passion, prejudice, or other improper motive Therefore, the defendant's exceptions are overruled and the case remitted to the superior court, with direction to enter judgment on the verdict for the amount above stated

Prohibition Against Disclosures Is Absolute

(Well vs Well (N Y), 136 N Y Supp 190)

The First Appellate Division of the Supreme Court of New York affirms an order dismissing an uncontested action for the annulment of a marriage because, it says there was no legal evidence of the existence of the disability of which the plaintiff complained There was evidence given by a physician, but that was clearly incompetent, and should not have been received Section 834 of the New York Code of Civil Procedure provides that a physician "shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity" That was precisely what the physician was allowed to do in this case It was of no consequence that the defendant was not present to object to the evidence The Code does not provide that such evidence may be received if not objected to The prohibition is absolute, that the physician shall not be allowed to testify, and it remains effective, unless the provisions are expressly waived on the trial by the patient The court should have refused to receive the evidence, and, if it was received inadvertently, should have disregarded it

Empiricism in Medicine

Dr H H **Martin**, Savannah, Ga If we must use drugs in our practice, we have the U S Pharmacopeia, the National Formulary, and the list of new and nonofficial remedies which have been examined and approved by the Council on Pharmacy and Chemistry of the American Medical Association We should withdraw our support from the so called remedies and cures which are manufactured or compounded for the sole purpose of making money and not for the purpose of healing the sick Let us, as medical men, entrusted with the health and lives of our fellow men, come to a fuller realization of our duties and responsibilities Let us shake off the superstitions and absurdities of empiricism, let us draw a sharper line between scientific and empiric medicine with "no compromise" as our slogan Let us exclude from our offices the voluble "detail man" and his wares, and the medical journals which are allied with the proprietary interests Let us also endeavor to have established, if necessary, one or more drug stores in every city and town in this country where drugs are dispensed on prescription only Let us endeavor to secure the enactment of a law in each state that will make the newspaper proprietor just as responsible civilly and criminally for the advertisements that go into his paper as he is for any article in the news columns

The Thyroid and Hyperthyroidism

Dr **Stuart McGuire**, Richmond, Va A patient with exophthalmic goiter ought to be kept under observation and carefully studied for some days before the surgeon decides on the character of the operation best suited to the individual and the safest time to perform it In the hands of experts, the mortality of operations for hyperthyroidism is now from 2 to 5 per cent, and 85 per cent of those who recover may be said to be symptomatic cures It is neither honest nor expedient to make light of the operation or to belittle its difficulties and dangers After a successful operation for hyperthyroidism the improvement in the patient is immediate and marked No operation in surgery produces such quick and brilliant results Tremor disappears, the pulse falls to normal, the eyes become less and less wild, and restlessness and irritability are replaced by quiet and composure The wound, as a rule, heals rapidly, and the patient is able to leave the hospital in from ten to fourteen days Though the patient is well from the operation, and though the acute symptoms are relieved, the patient should not return immediately to the ordinary activities of life It requires approximately the same time to recover from exophthalmic goiter as from a nervous breakdown from other causes A successful operation should be followed by an adequate period of rest

Vaccine Therapy

Dr. **Irvin E Colgin**, Waco, Texas The most uniform results obtained from the use of vaccines are in cases of pyogenic infection, especially those caused by staphylococci, such as furuncles and carbuncles This is due to two factors, the chronicity of the infection and the *uniformity of the* causative organism Success has also been the rule in treating cases of acne vulgaris In vaccine therapy success depends on (1) choice of cases applicable *to the use of* bacterial vaccines, (2) determination of the causative factor (do not depend on mixed vaccines, as usually if you eliminate the main factor Nature can take care of the balance of infection), (3) selection of the dose according to individual patients (do not follow set rules), (4) the interval between injections (make it long enough to let the body respond to the stimulation)

DISCUSSION

Dr. **J B Elliott, Jr**, New Orleans My results in the treatment of typhoid fever by the use of typhoid vaccines have been uniformly successful The cases have all terminated about the twentieth or twenty second day, and after three doses of vaccine have been given the temperature has generally fallen to normal I have failed to see any harm done in any case by the use of typhoid vaccines

Hydrothorax in Its Relation to Cardiorenal Lesions

Dr. **Frank A Jones**, Memphis, Tenn Hydrothorax is often an acute condition instead of part of a general dropsy Acute nephritis is often ushered in by an attack of acute edema of the lungs, followed rapidly by acute fulminating hydrothorax In all probability, the edema of the lung followed rapidly by hydrothorax is due to the same toxic agencies which, at the same time, produce the renal changes In these cases passive congestion, venous stasis, etc, have nothing to do with the production of the edema, the large black lung is analogous to the large red kidney When dyspnea is marked, either in cardiac or renal lesions, the patient should be examined for hydrothorax just as critically Hydrothorax, massive in nature, is often latent Saline cathartics and digitalis, when hydrothorax is present to any appreciable degree, are dangerous They invite edema of the lungs and paralysis of the heart

Relation of Gas Embolism to the Production of Artificial Pneumothorax

Dr **Stevens T Harris**, Highlands, N C The results of no other method ever employed can compare with the wonderful results obtained by this procedure It is the only real curative treatment for phthisis ever devised Artificial pneumothorax, like other surgical methods, has its dangers, of which the chief is gas embolism Nearly all the deaths due to the treatment have been caused by this condition The chances for gas embolism are remote after you have definitely proved that the pleura is free and that more or less of a cavity has been formed We have never seen it occur when this is the case, except when there were a thickened pleura and some adhesions, and when too high a pressure was suddenly produced.

Some Economic Questions Related to Syphilis

Dr **Isadore Dyer**, New Orleans Hospitals for syphilis should be established in every state, not as an incentive to vice, but as a deterrent If syphilitics were required to be hospitalized for the treatment of their disease, it would reduce the occurrence of syphilis and would encourage proper treatment While treatment may be of great importance, of more importance is the study of the ways and means to educate the profession and the public in the care and in the prevention of syphilis and its consequences

Hygiene of Syphilis

Dr **Oscar Dowling**, New Orleans As a preventive measure segregation of the prostitute class, while unsatisfactory and undoubtedly a legalization of vice, affords opportunity for medical supervision and treatment Stringent, practical regulations, humane, adapted to local conditions, and rigidly enforced, would give results worth the effort involved. But to be effective, there should be no favor, no laxity, no escape Certainty and justice should be the keynotes The best means of getting rid of syphilis or any similar disease is to educate the people by energetic, practical work Vigilance in the control of bad practices, activity in the practical things pertaining to home life, enforcement of every health ordinance and regulation are means which spread the gospel of cleanliness and health The hygiene of syphilis is the same as the hygiene of other contagious diseases From its nature, specific work should be done to enlighten every one as to its origin and to correct the false notion that it is contracted in one way

Treatment of Chronic Laryngeal Stenosis

Dr Homer Dupuy, New Orleans When a laryngeal stenosis is the result of hyperplastic changes, some form of dilatation is the most logical method of overcoming it Gradual, systematic dilatation by intubation offers favorable prospects of success The tube with a low retaining swell and a wide head would seem to meet a want in the treatment of this form of stenosis In children, hypertrophic laryngitis is largely responsible for a chronic laryngeal stenosis In this particular affection tracheotomy is more apt to induce connective tissue changes than to effect a final cure

(To be concluded)

10 Introductory Histopathologic Study of Paraplexus in Psychoses J A F Pfeiffer Washington D C
11 How Long Has Pellagra Existed in South Carolina? J W Babcock Columbia S C

3 **Heredity in Mental Diseases**—No attempt is made by Cotton to give any definite conclusions regarding the hereditary factors in the various psychoses He reviews some of the most important work done so far and outlines the methods to be pursued to obtain the best results in future work He also speaks of some of the difficulties to be met with, especially when analyzing the material as it comes from the field workers, and emphasizes the necessity of maintaining an open mind regarding these problems, and not to be too biased in attempting to make the facts fit the Mendelian laws At the same time, he recognizes that a comprehensive knowledge of the laws will assist materially in analyzing data and in arriving at practical conclusions He also feels that much valuable material will be obtained which will aid in solving the problems of prophylaxis and prevention of mental diseases An excellent bibliography is appended to Cotton's paper

7 **Hallucinations in Manic Depressive Psychoses**—In 800 cases in which the histories were studied by Pease, 219 or 27 3 per cent had hallucinations Of the 219 hallucinating cases 122 or 55 7 per cent recovered Of the 581 non hallucinating cases 298 or 53 4 per cent recovered It was found that these 800 cases represent only 609 persons Of the 609 persons, 182 or 29 9 per cent had hallucinations Of the 182 hallucinating persons 99 or 54 3 per cent recovered Of the 427 non hallucinating persons, 192 or 44 9 per cent recovered So far as hallucinations have any prognostic value at all, Pease says they indicate (1) a slightly better prognosis for the attack, and (2) a somewhat greater liability to recurrence of attacks But (3) the differences in percentage between the hallucinating and the non hallucinating cases is so slight as to suggest that if data from a much larger number of cases could be obtained these differences might disappear, in which case hallucinations would have no prognostic value.

8 **Association in Feeble Minded and Delinquent Children.**—The material of this study consists mainly of test records which have been obtained from 253 subjects All subjects were selected on the basis of backwardness in studies as rated by the teachers, the majority are also delinquents, having been committed on charges of truancy, disobedience, running away from home, theft, burglary, assault, etc In their ages 233 of the subjects range from 11 to 17 years, almost all the remaining twenty being one or two years below or above this range The conclusions arrived at are (1) that states of arrested mental development present certain fairly characteristic associational tendencies (2) These tendencies are characterized mainly by failures of reaction, non specific reactions, and certain types of individual reactions (3) The association test, as employed in the authors' study, is an aid in the diagnosis of feeble mindedness

9 **Cytology and Chemistry of Cerebrospinal Fluid**—In order to make a complete laboratory report of neurologic or psychiatric validity Karpas says it is essential to examine the blood and fluid for complement deviation, and, in addition to this, cytologic and chemical tests of the cerebrospinal fluid should be made An examination of the blood alone will throw no light on the psychiatric or neurologic diagnosis It must be also emphasized that in suspicious cases, several examinations of the blood and fluid should be performed The 100 cases of general paralysis studied by Karpas gave in 63 per cent a positive Wassermann in the fluid and blood, 7 per cent revealed a positive Wassermann only in the blood, in 16 per cent the Wassermann reaction was present only in the fluid, in 4 per cent of the cases, the Wassermann test in the blood and fluid was negative He has had no experience with incipient cases of general paralysis, forty nine out of seventy two cases were fully developed and only seven of twenty two general paralytics were in the last stage Some of the cases gave a negative Wassermann test in the blood, also there are other instances in which the Wassermann test was negative in the fluid, and again there are cases which show a negative Wassermann reaction both in the blood and fluid, and these findings bore no relation to the course and progress of the disease process In all cases, except two, lymphocytosis was demonstrated with varying intensity, but no distinct parallel with the course of the disease could be established In the majority of cases the four reactions were, as a rule, present Karpas is convinced that the cytologic reaction plus the globulin content are of profound significance and are always indicative of an organic process in the central nervous system In two cases of cerebral syphilis, which were confirmed by post mortem examination, the Wassermann reaction was present in the blood but not in the fluid, and globulin increase and lymphocytosis were manifested In chronic syphilitic endarteritis of a non active process and apparently healed gummata, the blood gave a complement deviation, the fluid was negative for Wassermann test, globulin was not increased and the cell count was very low, only three lymphocytes per cubic millimeter In other cases, in which the syphilitic process was relatively young or active, the results were the same as those obtained by Plaut The four reactions were not present in the two cases of tabes The alcoholic psychoses present no pathologic phenomena in the fluid however in some of the cases Wassermann reaction was present in the blood and in some instances a history of syphilitic infection was obtained Likewise arteriosclerotic and senile mental diseases and functional psychoses (such as dementia praecox, manic depressive insanity, etc) gave similar results In epileptic psychoses as a rule, neither the blood nor the fluid reveals abnormal constituents Three of twenty two cases of epileptic psychoses on the first examination showed some abnormal phenomena in the blood and fluid Under anti syphilitic treatment these pathologic manifestations disappeared The [illegible] laboratory cannot be considered as the ultimate [illegible] a for deciding disputed diagnosis of border [illegible] observations cannot be undermined, [illegible] can not be ignored, and the [illegible] phenomena should be [illegible] results can only be utilized

25 **Diagnosis of Conditions Associated with Obstruction to Outflow of Blood from Brain.**—Experience has led Crowe to conclude that any acute obstruction to the outflow of blood through the sigmoid sinus, jugular bulb or internal jugular vein on one side may be diagnosed by means of the following test 1 No appreciable evidence of stasis is seen in the retinal or supra orbital veins when one internal jugular is compressed with the finger 2 Pressure on both internal jugular veins at the same time produces a marked dilatation of the veins of the fundi and of the anastomotic vessels connecting the intracranial with the extracranial venous circulation 3 When the pressure is suddenly released on one side, while it is maintained on the other the engorged veins of the anastomotic system and the fundi will immediately empty If the results in any individual case differ markedly from those above, Crowe says, it must be concluded that there is either an anomaly of the intracranial venous circulation or some pathologic condition, which is obstructing the outflow of blood from the brain Crowe emphasizes that it is very important while making this examination that the patient should breathe freely and normally, that the collar should be loosened so as to expose the neck and upper part of the chest and that the fundi should be examined by the direct method, or with an electric ophthalmoscope while an assistant compresses the internal jugular veins with the tips of the fingers The compression, however should not be maintained longer than absolutely necessary, for it may be possible in this way to rupture a diseased vein or dislodge a portion of a thrombus

During the past two years Crowe has had an opportunity of making this examination in six cases in which there was an acute obstruction, on one side, to the outflow of blood from the cranial chamber In five of these cases the obstruction was due to a thrombosis, secondary to a chronic infection of the middle ear, and the test described above was employed in making the diagnosis In three instances the first symptoms of the thrombosis appeared several days after the radical mastoid operation and offered an excellent opportunity to determine the value of this sign

It is Crowe's custom to make this test before operation on all cases in which a sinus thrombosis is a possible or threatened complication The examination of each of these three cases before operation, indicated that the blood was passing freely into the internal jugular vein on both sides This was also the opinion of the surgeon at the time of the operation, although in each case there was a cholesteatoma which extended backward to the dura of the posterior fossa The wall of the sigmoid sinus and surrounding dura was thickened and covered with granulations Before the operation, however, there had been no elevation of temperature, and the test had indicated that the blood was flowing freely into the internal jugular vein on both sides, therefore, it was deemed advisable to leave the sinus untouched and await developments After a postoperative period of several days, free from discomfort or fever, the patient in each case began to complain of pain in the back of the head, there was a sudden elevation of temperature, a positive Kernig's sign, a low grade of choked disc, and some stiffness of the neck After excluding angina, pneumonia and disturbances of the digestive tract it was necessary in each case to decide whether these symptoms were due to 1 Serous meningitis with retention of pus in the operative wound 2 Localized basilar meningitis 3 Temporal lobe abscess 4 Cerebellar abscess 5 Sinus thrombosis On making the vascular test a second time it was found to be decidedly positive, i e, the stasis in the retinal and supra orbital veins was markedly increased by very slight pressure on the internal jugular vein on the healthy side, whereas at the previous examination the test had been decidedly negative.

The only conclusion from this result was that whatever other complications might be present, it was sure that the blood was no longer flowing freely into the internal jugular vein on the side of the operation The sinus was immediately exposed and opened, and in each case found to be thrombosed In one of the cases, however, even at the second operation the sigmoid sinus was fairly normal in appearance, and on incising it there was a gush of blood The cerebral end of the sinus was packed with gauze and the incision in the sinus wall enlarged downward By pressure on the upper part of the internal jugular vein in the neck pus was forced upward into the wound Further investigation disclosed a thrombus in the bulb which, however, was not purulent

27 **Endocarditis Lenta**—The results of Major's studies lead him to conclude that endocarditis lenta, caused by the *S viridans*, has a sufficiently distinctive picture to deserve recognition as a separate clinical entity That cases of chronic endocarditis may also be due to the *B Influenzae*, *S pyogenes*, or pneumococcus, is, of course, well known, but such cases should be distinguished from those due to *S viridans*, just as epidemic cerebrospinal meningitis, for example, is distinguished from meningitis due to the *B tuberculosis*, *B influenzae* or *S pyogenes* The coccus present in the cases cited by Major corresponds culturally to the organism described by Schottmuller as the *S viridans* No essential cultural differences have been noted between the *S viridans* and *M rheumaticus* Complement fixation tests in one case of endocarditis lenta showed the presence in the patient's blood of specific "antibodies '

28 **Defects in Mucous Membrane of Stomach**—Proceeding on the premises that all that is necessary for the healing of a gastric ulcer is for healthy mucous membrane to grow across its floor and remain intact, and as it seemed possible that the mucous membrane of the ulcer edges might be stimulated by scarlet red and thus accomplish the desired result, the authors fed dogs, in whom an artificial ulcer had been produced surgically, with a 1 per cent scarlet red in olive oil They found that the dyestuff is not toxic and apparently has no deleterious effect on either dogs or rabbits When given by mouth it is a fat selecting vital stain In the course of months the stain is gradually eliminated Subcutaneous and intraperitoneal injections stain only the fat in actual contact with the scarlet red oil solution The authors are unable to say whether the scarlet red has or has not, a definite stimulating action on the epithelium of defects in the gastric mucosa However, the scarlet red oil solution caused a more rapid and better developed growth of epithelium in the group in which it was used, than occurred in the duplicate group in which plain olive oil was used The results with dry powder were not so favorable experimentally, but this may have been due to the fact that the material was not continuously in con

tact with the denuded area They were unable to determine the relative effect of the scarlet red on chronic gastric ulcers, as it was impossible to produce chronic ulcers in dogs with controls of exactly the same size.

31 *Some Results of Treatment of Drinking Water of Baltimore by Means of Calcium Hypochlorite W R Stokes Baltimore

31 **Treatment of Drinking Water with Hypochlorite** —From the evidence at hand, Stokes says, it would seem that the use of the hypochlorite treatment of water has caused a general reduction in the intestinal and water bacteria, and that there has been a coincident decrease of the typhoid morbidity and fatality in Baltimore He advises that the figures should be studied for five year periods at least, however, before coming to any final conclusions concerning this effect of the hypochlorite on the constituents of the drinking water and on the number of cases of typhoid in the city The hypochlorite treatment was begun about the first of June, 1911, and from then on the number of typhoid cases reported monthly during 1911 is much smaller than the corresponding months for 1910, and it also shows a considerable drop as compared to the average cases for 1906 to 1910 inclusive In August, 1910, there were 473 cases, in August 1911, only 280 cases The total number of cases of typhoid for 1910 was 1,891, and although the hypochlorite treatment was not begun until June, 1911, the number of reported cases was only 1,201 for this year The total number of deaths for 1910 was 235 During 1911 the number of deaths from typhoid was only 154, although the hypochlorite treatment as mentioned above was only begun about the first of June.

34 *New Reagent (Tolidin) for Detecting Occult Blood R F Ruttan and R H M Hardisty Montreal
35 Factors Frequently Overlooked in Early Diagnosis of Pulmonary Tuberculosis W E Ogden Gravenhurst Ontario
36 Scoliosis. A M Forbes Montreal

34 **New Reagent for Detecting Occult Blood** —The substance used by Ruttan and Hardisty for detecting occult blood is tolidin or orthotolidin, a crystalline basic body of the aromatic series, with melting point 129 130 C, very slightly soluble in water, easily soluble in alcohol and ether and closely allied to toluidin and benzidin It is said to be a reagent of very great delicacy for detecting blood in watery solution and, in addition to this, it is superior to the reagents in general use for clinical work It is greatly superior to all the reagents for detecting blood in urine, and while benzidin, which is easily the best of the well known reagents for clinical work, is quoted here as being equal to tolidin for the detection of blood in feces and stomach contents, this is true only for freshly prepared solutions of benzidin, older solutions losing 50 per cent. of their delicacy in twenty four hours, whereas tolidin will remain unchanged for from three to four weeks, an important fact, adding to the ease with which the test can be carried out Another point in favor of tolidin is that when the blood is in small quantity, the reaction increases gradually in intensity and persists longer than with the other reagents, so being more easily read.

It was found that guaiacum detected blood in dilutions of 1 to 50,000, benzidin, 1 to 700,000, tolidin, of 1 to 7,000 000 phenolphthalein, of 1 to 10 000,000 and even more As an agent for detecting blood in watery solution phenolphthalein was found to be much the most delicate, in fact the test had to be carefully controlled to be sure the positive reaction was due to blood, for it was found that the ordinary distilled water of the laboratory gave a pinkish color, positive reaction, due to some infinitesimal trace of iron or copper salt and so all the distilled water had to be redistilled in glass before being used Guaiacum and benzidin, when positive, give a prompt reaction which, however, depending on the dilution, does not last very long With tolidin, the color, a green to a blue black, depending on dilution does not develop quite so rapidly appearing more gradually and increasing in intensity, the colors lasting a much longer time, even several hours

56 *Coagulation Time of Blood in Lobar Pneumonia A R Dochez New York
57 *Carbon Dioxid Content of Blood in Pneumonia F W Peabody New York.

48 **Chemo Immunologic Studies on Localized Infections** — It was found by Lamar that virulent pneumococci injected into the cranial or spinal cavities of monkeys produce constantly a meningitis closely resembling pneumococcus meningitis in man, except that the experimental disease pursues a more rapid course to the invariable death of the untreated animal An homologous immune pneumococcus serum injected into the spinal canal exerts a restraining influence on the disease to the extent that when employed early it prevented exceptionally, the occurrence of infection and thus saved the life of the animal, and when given later it at first retarded the disease but subsequently exerted no beneficial action and was powerless to save life A mixture of sodium oleate, immune serum and boric acid exerted regularly a more powerful action than immune serum alone, and not only prevented the occurrence of infection but also, when administered repeatedly, arrested the progress of an actually established infection and led, often, to the enduring and perfect recovery of the inoculated animal It is proposed to employ a similar mixture in the direct treatment of pneumococcic meningitis and possibly of still other accessible local pneumococcic infections in man

49 **Pigment Formation in Liver During Autolysis** —Without claiming any close analogy between the autolytic changes and pigmentation in pathologic processes, the authors believe it has been shown that iron-containing, as well as other kinds of pigments, may be formed during the autolytic degeneration of parenchymatous cells independently of the hemoglobin in the blood stream and hence may be derived from the protein constituents of the cell itself

50 **Nerve Fibrils in Sino Auricular Node** —Aside from the nerve fibers which enter the pace making node from the subepicardium, the authors observed within the limits of the node a few ganglionic cells and a plexus of moniliform nerve

fibrils in very close relation to its muscle fibers, hence, they claim that the sino auricular node, like the auriculo ventricular, may be considered from a histologic standpoint a neuro muscular organ

53 **Toxic Substances Produced by Pneumococcus**—Cole is convinced that the filtered blood serum of rabbits infected with pneumococci is not toxic Extracts of pneumococci prepared by keeping emulsions of the bacteria in salt solution at 37 C for varying periods of time may be toxic, and when injected intravenously into guinea pigs, may produce a train of symptoms followed by acute death resembling that seen in acute anaphylaxis Such extracts, however, are not uniformly toxic and it has been impossible to discover the exact conditions under which such extracts become toxic. When the centrifugalized peritoneal washings of guinea pigs infected with pneumococci are injected into the circulation of normal guinea pigs, these animals very frequently exhibit symptoms like those seen in acute anaphylaxis, and a considerable proportion of the animals die acutely When pneumococci are dissolved in dilute solutions of bile salts and the solution resulting is injected intravenously into rabbits and guinea pigs, these animals show with great constancy the same symptoms that are seen in acute anaphylaxis The solution of pneumococci in bile may occur in ten minutes at 37 C or in half an hour on ice This is considered evidence that the toxicity of the solution does not result from digestion of the bacterial protein, but is due to substances preformed in the bacterial cells and set free on their solution The toxicity of the solution is diminished or destroyed by heating to 55 C or over

54 **Protective Substances in Human Serum.**—Dochez's experiments demonstrate that protective substances are usually present in the blood of patients recovering from lobar pneumonia As a rule, the appearance of protective bodies in the blood, when demonstrable, coincides rather sharply with the period of critical fall in temperature and the disappearance of symptoms These substances are not present in the blood in any measurable degree before the crisis, but afterward they may reach a considerable concentration In certain instances, protective substances either become evident some time after the occurrence of the crisis, or cannot be demonstrated at any period of the disease Experiments in which it is possible to test serum against an homologous strain of pneumococcus yield, in the majority of cases, evidence of the presence of protective bodies, whereas in those in which stock cultures are used, the serum, as a rule shows no protection The development of specific protective substances in the serum of patients with lobar pneumonia suggests that these bodies may play a part in the mechanism of recovery

55 **Pneumococci in Circulating Blood.**—Studies of the bacteriology of the blood were made by Dochez in thirty seven cases of lobar pneumonia The pneumococcus was isolated from the blood in approximately 50 per cent of the cases studied The course of infection in individuals with pneumococcus in the blood was more severe than in those in which no organism could be cultivated from the blood Seventy seven per cent of the patients with positive blood cultures died, and 79 per cent of patients with negative blood cultures recovered In fatal instances of pneumonia, in which the pneumococcus was found in the blood, the number of organisms per cubic centimeter of blood was very high in the last stage of the disease In individuals dying of pneumonia without blood infection, the disease was characterized by a rapid spread of the local process in the lungs It is not unlikely that the symptoms of collapse developing on the fifth or sixth day of lobar pneumonia, are often the expression of serious invasion of the blood by the pneumococcus In other instances, they mark an extension of the local process in the lungs Strains of pneumococcus isolated from the blood of patients with lobar pneumonia were usually of high animal virulence In a few instances in which the organism isolated from the blood was of low virulence for animals, the patients recovered The protective power of a univalent antipneumococcus serum was tested against nineteen strains of typical pneumococcus and against four strains of closely allied organisms The serum manifested some degree of protection against twelve out of nineteen strains of typical pneumococci No protection was observed against the atypical organisms In eight instances the degree of protection obtained was high, in three low, and in one there occurred only a prolongation of the period of life of the inoculated animal

56 **Coagulation Time of Blood in Lobar Pneumonia**—The coagulation time of the blood was found by Dochez to be generally prolonged during the acute stage of lobar pneumonia, returning to normal during the period of convalescence There seems to be a simultaneous increase in the quantity of circulating fibrinogen The lengthening of the coagulation time is probably due to an increased formation of antithrombin The source of the increased antithrombin and fibrinogen is probably the liver, and the stimulus to increased production of these two substances is due to the nature of the infecting organism

57 **Carbon Dioxid Content of Blood in Pneumonia**—A diminution in the carbon dioxid content of the blood is held by Peabody to be a constant feature in pneumonia Occasional cases, however, may fail to show low carbon dioxid The carbon dioxid in the blood bears little definite relation to the severity of the disease, except that it tends to be lowest in severe cases and in the terminal stages of the disease There is less deviation from the normal in short or mild cases The diminution in the carbon dioxid in the blood bears no immediate relation to temperature, as it may persist for some days after the patient is afebrile The diminution in carbon dioxid corresponds to the other evidences of metabolic changes in infection and, like them, may be even greater after than during the febrile period The changes in the carbon dioxid content of the blood run parallel to the output of ammonia in the urine The carbon dioxid appears to bear no relation to chlorin excretion In two unusual cases the carbon dioxid content of the blood was normal or above normal This was associated with a very low oxygen content of the venous blood

evident that some affection

the first symptom in 69 per cent of the patients recorded, and hence the constant tendency to confound this disease with true bulbar palsy

In 31 per cent of the patients the records show that the first weakness was felt in the arms or in the legs, most commonly in the legs, and that for several days, weeks, or even months before any cranial nerve symptoms developed, a very decided weakness of the limbs, leading to an almost complete paralysis, had occurred In very many cases this weakness, being of a functional nature not attended by atrophy or fibrillary twitchings or reaction of degeneration, and not attended by any uniform disturbances in the reflexes either of the nature of the loss of reflex or in the exaggeration of reflex has led to the diagnosis of general neurasthenic weakness or of hysteria Starr calls particular attention to the form of myasthenia in which weakness of the limbs without any cranial nerve involvement constitutes the predominant symptom, because he believes that many cases of this character have escaped recognition, and this is the mode of onset in one third of the cases

A symptom to which very little attention has been given, but which has been recorded in an astonishingly large number of cases, both as an early sign and as a constant symptom, is headache This is generalized and is increased by mental effort or by physical exertion While an enlargement of the thymus gland has been observed in about 28 per cent of the patients examined, its absence in 72 per cent of the patients seems to afford positive evidence that it is not essential to the development of the disease In almost all recent autopsies the infiltration of the muscles and all of the internal organs of the body by small cells clustered about the lymphatic system and infiltrating the tissues widely, which have been termed lymphorrhages, has been observed The pathology of the disease is still obscure Many forms of treatment have been employed in myasthenia The use of the organic extracts, especially of thyroid, of pituitary and of parathyroid, seems to have been universal in the past ten years But so far as the results are recorded this treatment has not been successful Strychnin has been employed by almost every observer and the reports of the effects are conflicting Calcium lactate has been employed in a few cases with apparent benefit All authorities agree that rest in bed without use of the eyes and without talking is essential to any improvement

80, 83 and 84 Abstracted in The Journal, October 26, pp 1563 and 1564

86 **Tincture of Iodin for Blistered and Abraded Feet.**—In order to ascertain whether tincture of iodin would be beneficial in the treatment of "sore feet," preventing simple abrasions of the skin from becoming ulcerated and hastening the cure where considerable inflammation existed, Richardson gave the abraded surface a preliminary scrubbing with soap and warm water, but later, in order to see results under conditions simulating those of actual service, he simply applied thoroughly over the affected areas, with a camel's hair brush or cotton swab, the official 7 per cent tincture of iodin and allowed it to dry In cases in which the blisters had not ruptured, they were first painted and then incised by a sharp pointed sterilized bistoury, care being taken to enter the blister under and beyond its raised surface After expressing the serum, the incision was given a second coating In cases of simple abrasions of the superficial layers of the skin, no dressings, ointments or powders were applied and the stockings were replaced, the men being told to report the following day Those who reported were invariably well and needed no further treatment

Where blisters had broken or ulcers had formed, some sort of protective dressing was found necessary and for this purpose nothing seemed to surpass zinc oxid adhesive plaster, properly cut and fitted to the part The method employed consisted of placing two or three small squares or layers of plaster together, folding on the non adhesive surface, and cutting with scissors a circular opening slightly larger than the inflamed area it was desired to protect Care should be taken that the pad is not too large or too thick and that it is applied without wrinkles Where there was considerable exudate, Richardson applied a few layers of gauze over the ulcer, being particular that they were not wide enough to prevent the plaster from adhering to the healthy skin In this way all pressure from the shoe was overcome, thus preventing any direct, constant irritation which could interfere with the healing process For inflamed callosities or bunions, adhesive plaster applied in the manner described gives immediate relief and renders a man capable of walking with comparative comfort

1 **Hydatid Cysts of Lung**—Of all cases of hydatids, Griffith says, about 10 to 15 per cent occur in the lung In the lung the cyst wall is thin and poorly supported by the surrounding tissue This thin adventitious cyst has special relations to arteries, veins and bronchi, the last often opening directly into it The lung is vulnerable, and a further peculiarity results from changes liable to occur in it, i e, pericystic pulmonary congestion, which may sometimes give rise to hemoptysis, and even pneumonia and to pericystic sclerosis The hydatid cachexia (weakness wasting, anorexia, etc), is considered by some authors to appear earlier in lung than in liver cases Degenerative changes sometimes occur, death of the parasite with inspissation of the contents which become colloid, caseous or even calcareous, the cyst shriveling up

In its early stage pulmonary hydatid is compatible with perfect health Any of the following phenomena may occur Cough—At first usually dry and jerky, later it may be very distressing Ill-defined uneasiness or actual pain Hemoptysis—(a) In an early stage, even when the cyst is less than a pea in size, hemoptysis may result from congestion of the surrounding lung, (b) with rupture of the cyst occurring either naturally or as a result of an operation, violent, even fatal, bleeding may occur, (c) occasionally repeated hemorrhage may persist for months, or years, after rupture Pleurisy in the serosa over the cyst with or without effusion If the cyst grows outward toward the wall of the chest, it may simulate pleural effusion or may cause erosion of bone and arching of the thorax, and rarely may point and burst externally Dyspnea—If the cyst be very large or near the hilus If the parasite dies the cyst shrinks and its contents become colloid or calcareous Pneumonic Attacks—Diffuse or massive pneumonia, sometimes resembling frank lobar pneumonia Rupture—Rupture of the cyst may occur, (a) into the adventitious cyst, (b) into a bronchus, generally the result of (a) this may result in spontaneous cure, (c) into the pleura, often with fatal result, or (d) into both bronchus and pleura leading to pneumothorax or pyopneumothorax As a rare complication rupture into other organs may occur Urticaria—Probably due to absorption of fluid Changes in the blood—(a) Eosinophilia, (b) antibodies in the serum Secondary infection with hectic fever (usually the result of fissured rupture) Tuberculosis may occur as a secondary infection either in the neighborhood of the cyst or at a distance Hydatid cachexia is said to develop earlier, and to be more marked in the case of the lung than of other organs, often, however, the patient appears in robust health

In many cases, even when the cyst has attained quite a large size, there may be practically no signs This is especially the case when the cyst is deep-seated At other times the following may be observed Dulness—Sometimes typically circular in outline over the circular area in which the spherical cyst meets the chest wall Hydatid thrill or fremitus—Over the dull region vocal fremitus and breath sounds may be feeble or absent, and, in some cases, there may be exquisite pectoriloquy Nearby pleuritic friction may be heard or fine crackles in the compressed lung If the cyst be large the heart and other organs may be displaced. If the unruptured cyst be very large the intercostal spaces may be obliterated, and the chest wall may bulge, more rarely we may find such signs as dysphagia difference in the pulses, etc Other special signs may be associated with complications, e g, fetid expectoration, pleural effusion, urticaria After rupture, we get the signs of a cavity, and if sepsis occur, râles and rhonchi In far advanced cases as in other forms of lung disease, clubbing of the fingers is seen In making the diagnosis we have the following aids (1) Diagnostic tuberculin test, (2) Roentgen ray examination, (3) blood examination.

40 **Adrenal Cortex, Its Rests and Tumors**—Glynn summarizes his paper as follows The adrenal cortex and medulla have a different development and different functions, the former is especially connected with growth and sex characters, the latter with blood pressure Tumors are rare, primary malignant tumors especially so, the most usual being (a) round celled sarcoma, (b) adrenal hypernephroma, an epithelial like growth of cortical origin Sarcomata are the commoner, they are more frequent in children, especially in male children Adrenal hypernephromata are five times more frequent in female children, though in adults they are slightly commoner in males Sarcomata and adrenal hypernephromata differ histologically, and in children at any rate, differ clinically Adrenal hypernephromata are associated with sex abnormalities, almost invariably in children, usually in adult females before the menopause, but apparently never in adult females after the menopause, or in adult males Adrenal rests or bilateral hyperplasia of the adrenal gland is found in at least 15 per cent of female, but only 0 70 per cent of male pseudohermaphrodites Hyperplasia and hypernephromata of the adrenal cortex in females are usually associated with a diminution of certain female and the development of certain male sex characters The converse rarely occurs The only conditions in which some female sex characters are constantly acquired in males, or male sex characters fail to develop, are after castration performed before puberty, and occasionally in acromegaly Premature development of female sex characters in females may occur with certain ovarian tumors, and of male sex characters in males with certain tumors of the pineal gland, adrenal cortex and testicle In children and young adult females where the sex abnormalities are acquired there is usually unilateral malignant cortic l neoplasia

The neoplasia probably directly or indirectly causes the abnormalities In pseudohermaphroditism the sex abnormalities are mainly congenital and the adrenal lesions, if any, are bilateral cortical hyperplasia or cortical rests The hyperplasia possibly directly or indirectly causes the abnormalities, or some of them Rests from the adrenal cortex are common in certain localities, especially in infancy, except in the kidney They are usually of minute size, and are not associated with sex abnormalities unless there is much enlargement, when such may sometimes occur in pseudohermaphrodites The enlargement of the adrenal cortex during breeding, pregnancy and after castration and the small size in deficient sexual development are additional evidences of the connection of the cortex with sex characters. The functional association of the adrenal with the pituitary and other ductless glands, and the appearance of certain sex abnormalities in acromegaly, indicate that a true solution of the connection between the adrenal cortex and sex will only be found when the interrelationships of the various ductless glands are better understood Certain facts are opposed to the hypothesis that renal hypernephromata arise from the remnants of adrenal cortex, viz.—(a) The great dissimilarity in microscopic structure between hypernephromata of the renal and adrenal glands (b) Renal hypernephromata apparently never influence growth or sex characters (c) The difficulty of explaining why adrenal rests, though comparatively rare in the kidney, should produce such a common tumor as the hypernephroma, by far the commonest renal tumor, while adrenal rests in other localities, though comparatively common, especially in early life, should, like the adrenal gland itself, so rarely produce tumors either benign or malignant These considerations support the statements of Stoerk, Zehbe and Wilson and Willis, who maintain that renal hypernephromata rarely if ever arise from adrenal rests Adrenal rests in the ovary are exceedingly uncommon The ovarian hypernephroma does not produce the characteristic sex abnormalities, it probably arises from the lutein cells of the ovary itself

41 **Antigen Treatment of Enteric Fever**—Sadler takes exception to the name of vaccine treatment in typhoid He prefers the term "antigen treatment" for the object of the treatment is to produce such antibodies in the patient's system as will help him to deal with the infection from which he is suffering, a use to which vaccine proper is never put If the case appears to be a severe one, and especially if it be of the cerebral type with muttering delirium, he gives half the ordinary initial dose, that is to say, 1,000,000 bacilli to an adult and proportionately less to children If on the other hand, the patient seems not unduly ill, and especially if he is admitted within the first fourteen days, he gives 2,000,000 bacilli on admission to an adult, and proportionately less to children In the less severe cases the initial dose of 2,000 000 is the largest which is given throughout the disease, and the second and subsequent injections are of 1,000,000 bacilli only Sadler thinks one of his cases, in which there was a relapse, makes it advisable, even if the temperature has fallen to normal within five days after the first injection, or has assumed a convalescent type, to give at least one reinjection with a view to preventing relapse So none of his patients now get less than two injections unless the case is of such a serious nature as to terminate fatally before the fifth day after admission One of the difficulties of the treatment in the cases beneficially affected by vaccine is that the patient begins to be hungry before his tongue justifies any material increase in his diet, and in hemorrhage cases long before the bowel is likely to be strong enough to bear the diet which the patient desires Of this Sadler feels sure, that he would now not be justified in withholding the vaccine treatment from any case of typhoid he came across, for it is impossible to foretell how severe an individual case is going to be, and even with the severe cases by administering smaller initial doses of vaccine, there is reasonable prospect of safety, and the patient is none the worse for having received the vaccine

42 **Myotonia.**—Griffith reports a case which presented symptoms of myotonia in a pronounced form, along with marked atrophy of some groups of muscles and an enlargement of those of the calves In this case there was much from the clinical side to make him suspect that the symptoms of myotonia were associated with those of pseudohypertrophic palsy, but the increase in the knee jerks, the age of onset, the distribution of the atrophy and especially the absence of wasting of the lower part of the pectoralis major made him hesitate to conclude that this was the case The histologic examination appears definitely to exclude this affection and to show that there was a real enlargement of the muscular fibers, and that any increase in the general mass of the muscle was not due to a fatty or fibrous infiltration. Following Rossolimo and modifying his title to the special conditions met with in his patients, Griffith calls the case one of myotonia atrophica et hypertrophica

44 **Paroxysmal Bradycardia**—The first case described by Laslett exhibited sinus arhythmia of a grade which is unusual at any age and very rare beyond middle life During the long auricular pauses multiple ventricular extra systoles occurred The patient suffered from attacks of giddiness which it is suggested were due to cerebral anemia induced by the long intermissions of the pulse The longest intermission so far observed was two and a half seconds in duration The arhythmia temporarily disappeared after the administration of atropin, and was therefore in all probability vagal in origin In the second case a true bradycardia of almost regular rhythm was found shortly after one of the cerebral attacks from which the patient suffered It is suggested, though not proved, that the infrequent rate of the heart was due to increased inhibition

47 **Digitalis Preparations Employed in Medicine**—Pharmacologic and clinical investigations, Dixon says, have not made a clear case for the substitution of "active principles" for Galenical preparations of digitalis in the treatment of patients These active principles are for the most part just as irri
as the infusion or tincture, they are nei relia
constant in action than a properly s actu

are they absorbed more rapidly, they have the same tendency to accumulate and are much more expensive. The one advantage that certain of them may possess over the pharmacopeial preparations is that they may be given intravenously without ill effects.

50 *The Tuberculin Reactions. J. Castaigne and Gouraud.
51 *Compulsory Declaration of Tuberculosis: Its Objects and Limitations. G. Kuss.
52 *Arrest of Acute Tuberculosis by Artificial Pneumothorax. L. Rénon.

50. **Tuberculin Reactions.**—This article explains the principles on which the various *reactions to tuberculin are based* and the different technics and indications in different cases for the subcutaneous, ocular, nasal, cutaneous or intradermal methods.

51. **Compulsory Declaration of Tuberculosis.**—Kuss' address was presented at the Tuberculosis Congress at Rome last April. He insists on the necessity for compulsory declaration of every death from tuberculosis and disinfection of the premises. The head of the family and the patient should be *informed* when tuberculosis is diagnosed but compulsory declaration is of little use. Special advantages should result for the patient when the head of the family informs the proper authorities, but this *should not be made compulsory*. The patient and family should be instructed in means to prevent infection of others, and health officials should be provided who will disinfect the premises in a discreet manner without complicated apparatus, especially when a tuberculous person changes his residence. Kuss thinks it would be an excellent plan if once a year physicians filled out a general question blank stating the number of cases of pulmonary and laryngeal tuberculosis they have encountered, not naming their patients, these data to be preserved in the bureau of vital statistics and bureau of sanitary house inspection.

52. **Artificial Pneumothorax in Galloping Tuberculosis.**—*Rénon* says that he has seen over 120 articles on therapeutic artificial pneumothorax in the current literature of the last five months, and he quotes arguments that have been presented against this method of *creating a new morbid condition in* order to cure another—the danger of whipping up a process in the other lung or bringing on heart trouble, the tediousness of the treatment and its expense—but against all these arguments there is the record of great benefit realized. This is particularly striking, he declares, in the cases of acute tuberculosis *which have proved rebellious* to all other measures. In cases of galloping pulmonary tuberculosis in which the process continued a progressive course in spite of all treatment and a fatal outcome in four or five weeks seemed certain, he has witnessed the immediate arrest of the progressive course under the artificial pneumothorax. Even if there are a few pleural adhesions *preventing the total collapse of the lung* the partial collapse answers the purpose, and it may become total as the adhesions stretch or break. It may thus permit the gaining of precious time which will *allow other* measures a chance to display their efficiency. It is possible, Rénon adds, that these acute forms with rapid softening of lung tissue and tendency to severe hemoptysis may prove to be the special indication for the therapeutic pneumothorax, while we are waiting for the specific remedy that will cure tuberculosis.

Bulletin de l'Académie de Médecine, Paris

5 *Blood Borne Origin of Appendicitis. (Origine hématogène de certaines appendicites aigues.) F. Widal and *others*.
54 *Epilepsy. (Genèse et traitement de l'épilepsie commune.) M. de Fleury.

October 29, No. 35, pp. 325-354

55 *Transfusion of Blood After Excessive Uterine Hemorrhage. (Transfusion directe du sang après hémorragie par décollement du placenta normalement inséré.) Oui.

53. **Blood Borne Infection as Cause of Appendicitis.**—Widal reports a case in which the blood borne origin was unmistakable as paratyphoid B bacilli had been *found in the blood* two weeks before the onset of the appendicitis. There had been two weeks of apparently typical typhoid fever before the appendicitis developed. It *proved fatal in two days and necropsy* disclosed extensive lesions in the cecum and appendix with pure cultures of the above bacilli while the rest of the intestines were apparently sound. (See Paris Letter, p. 1986.)

54. **Treatment of Epilepsy.**—De Fleury ascribes epilepsy to a meningo-encephalitis which may have developed before birth. The *seizures are brought on by auto intoxication,* generally of intestinal origin. We are powerless against the organic irritability of the motor zone, except with bromids and other sedative measures, but we have a number of weapons at our disposal to combat the digestive intoxication and thus effectually eliminate one extremely important factor in the manifestations of epilepsy. He reports excellent results from treatment on these principles in thirty seven cases. The main reliance is on a diet to avoid generation of intestinal poisons, thus discarding all foods of animal origin, including milk, eggs, fish and meat. Milk and eggs are peculiarly liable, he says, to generate the poisons and thus bring on the seizures, so he prohibits them entirely until the patient has outgrown the seizure habit. The diet should consist of vegetables, salads, fruits, raw and cooked, starches, honey and preserves, with sweet and diuretic drinks to a total of a liter a day. More fluid than this might have an injurious influence by raising the blood pressure. The vegetable diet is supplemented by lactic ferments to transform the intestinal flora. None of his patients seemed to lose weight or suffer on this diet. He thinks it might prove effectual also in warding off eclampsia, his experiments with a fox terrier inclined to "fits" gave very encouraging results.

55. **Transfusion of Blood for Puerperal Hemorrhage.**—The healthy young woman in question was in labor with her sixth child when the normally implanted placenta separated prematurely and excessive hemorrhage followed. The pulse was 140 and the patient too exsanguinated to rally. The right radial artery of the husband was then sutured to the woman's right median cephalic vein, according to Carrel's technic except that two stitches instead of three were taken. The anastomosis was done under local anesthesia for the husband and no anesthesia for the woman. After five or six minutes her lips turned pink, her eyes opened and the pulse became perceptible once more. The donor's radial artery was rather small and seemed to contract occasionally, and the transfusion was kept up for an hour. The parts of the vein and artery utilized for the anastomosis were resected and found apparently *normal*. The woman's convalescence proceeded undisturbed thereafter. *An* important point in the technic of the anastomosis is to strip both artery and vein of adventitia.

October 20, No. 42, pp. 661-676

57 Chronic Addison's Disease: Three Cases. (3 cas de syndrome d'insuffisance capsulaire chronique.) C. Mongour.

56. **Antitoxin Treatment of Diphtheria Paralysis in Adult.**—The patient was a man of 34 who developed diphtheria after the death of a child from the disease. He was given three injections of antitoxin and seemed to have quite recovered by the end of a week. But a few days later paralysis of the velum, eyes and limbs became evident, closely resembling the motor disturbances of tabes. He was given 140 c.c. of antitoxin in the course of a month by subcutaneous injections and seemed entirely cured by the end of the second month. To avoid danger of anaphylaxis, the first injection of 20 c.c. of the antitoxin after the paralysis had developed was preceded by injection of 1 c.c. The intervals at *first were from three to* five days. The paralytic phenomena continued to progress the first week, but then were arrested and soon began to retrogress. Several *other cases in Auché's experience* have confirmed the benefit from systematic antitoxin treatment in diphtheric

paralysis He adds that a prophylactic injection when the first case developed in the family might have warded off the father's entire sickness

58 ***Injury of the Vagus Nerve*** —Bérard and Chalier had their attention called to this subject by eight experiences in their own service, in two the tenth nerve had to be resected and in six the nerve was injured more or less during an operation in the region They have found on record seventeen cases of traumatic injury of the vagus in the neck and fifty of operative resection The details of this material are tabulated for comparison They have also found a number of cases in which the vagus nerve was irritated The outcome of the traumatic or operative lesions of the cervical vagus was surprisingly favorable in nearly every instance, except the gunshot wounds only six of the seventeen patients in this group survived, one being left with paralysis of the left vocal cord Section or resection of the cervical vagus does not seem to cause any immediate trouble on the part of the respiration In seven cases pneumonia developed which was ascribed to this cause but analysis of the cases shows other conditions ample to explain the pneumonia in all but two cases, in which this was not so evident Unilateral vagotomy has even less of an immediate effect on the digestive apparatus than on the heart and respiration Section of the nerve thus is shown to be free from gravity, whether the nerve is sound or degenerated The absence of complications renders it unnecessary to suture the nerve after it has been severed, but this has been done in several cases, and is a legitimate measure when conditions render it possible Reich declares that irritation of the vagus has more serious effects than section, but sifting the cases on record shows that the nature of the irritation determines the severity of the resulting injury, ligating or pulling on the nerve or crushing are more liable to cause trouble Exposing the nerve and mild traction on it does not seem to have any effect on the organs innervated by it By avoiding severe irritation there is comparatively little danger At the same time it is better to sever or resect the nerve in operations in this region rather than to risk irritating it by exposing and pulling on it In any event it should never be ligated or seized except under direct visual inspection as otherwise there may be danger of seizing the nerve too roughly and thus producing a reflex syncope which may be very grave As a rule slight irritation of the vagus modifies the respiration rhythm and causes a spasmodic cough which should be a warning to the surgeon If syncope develops from the reflex irritation it may be wise, besides the usual measures for resuscitation, to sever the nerve In certain cases immediate section of the nerve arrested all the phenomena from the irritation, but this is scarcely necessary Tracheotomy is never needed for the purpose as the trouble is not a mechanical interference with respiration

59 **Osteoplastic Amputation.**—Imbert gives an illustrated description of the technic for osteoplastic amputation of the leg above the knee, and Cotte reports two cases in which he grafted a thin plate of bone from the tibia on the stump, or the epiphysis from the tibia, permitting weight bearing He regards this free epiphyseal osteoplastic operation as an excellent means to close the marrow canal and supply a bone stump the architecture of which seems to be especially designed for weight bearing

60 **Tuberculosis of the Nasal Accessory Sinuses** —Collet says that he knows of only thirty cases of this kind and recovery is reported in only five Treatment must consist in ample exposure and removal of all the diseased tissue He reviews the various cases on record but seems to have no personal experience to report

77 Importance of Artificial Feeding on Biologic Properties of Young Organism (Einfluss von künstlicher Ernährung auf biologische Eigenschaften des Organismus in dessen frühem Alter) T A Ossinin

71 **Acute Rheumatism with Subcutaneous Nodules in Children.**—Berkowitz reports five cases and compares them with seventy three in the literature in which small nodules developed symmetrically beneath the skin on or around the smaller joints in children who had had acute articular rheumatism in a severe form *Endocarditis or pericarditis was evident in* 89 per cent of the total seventy eight cases, plus chorea in twenty four cases, with chorea alone in three, and complications on the part of the heart alone in forty one The children were between 8 and 14 in most of the cases The nodules cause no pain or other disturbance and generally retrogress entirely after a few days or months *Berkowitz cites from* Dunn's article, "Rheumatic Fever in Children" in THE JOURNAL, Feb 9, 1907, p 493

72 **Nursing Allowances** —R S the
results of the workings of ng
mothers which has been
small allowance is given to
a certain amount as long
have to bring the infant

allowance is given them, and this medical oversight is by no means the least useful *factor in the nursing premiums* The women are given 25 or 50 cents a day and an additional 10 cents for the first child and about 8 cents for each later child. The annual number of infants ranged from 761 to 824, and the total expended was over $6,000 in 1910 The "consultations" are held at four different points in the city once or twice a week, in the afternoon The educational effect is regarded as of great value, and the children now 2 or 3 years old that had the advantages of the supervision during their early infancy *seem to be much above the average in health and alertness* over other children in their class The total material is tabulated from various standpoints

73 **Serotherapy of Epidemic Meningitis**—In the case reported by Levy an infant three and a half months old developed severe meningitis with paralysis of one side Meningococci were found in the spinal fluid on lumbar puncture, and no benefit was derived from the usual measures, hexamethylenamin, etc As the condition was growing rapidly worse, Levy introduced the needle into the lateral ventricle and injected 8 c c of antimeningococcus serum This was done the sixteenth and seventeenth days of the disease *At one stroke the clinical picture became transformed* The fever dropped, the paresis improved, and all the symptoms disappeared so rapidly that the child seemed to have entirely recovered by the sixth day thereafter Levy gives an illustration of the route for puncture of the lateral ventricle through the fontanel, the child lying on the side of his head He has done this operation on four children with a total of thirty punctures and fourteen injections, without ever experiencing any untoward by effects, except that in this case at the second puncture, as the fluid did not flow promptly he thought he was not in deep enough, and pushed the needle in a little farther, bringing blood He had evidently injured the choroid plexus, but it did not seem to do any harm in this instance Netter has reported ten cases without by effects Fischer has reported a case of erythema, sweating and foam at the mouth after an injection of the kind preceded by rinsing out the ventricle with salt solution, and he had left a large amount of the antiserum in the ventricle Levy warns expressly *against any such procedures and against* injecting any more fluid than is withdrawn The destruction of the cocci by the antiserum may flood the organism with their endotoxins and thus induce a temporary aggravation of the condition He reiterates in conclusion that the experience he relates confirms the tolerance of infants for injections into the lateral ventricles, and that it may have life saving value in otherwise hopeless cases The technic is not always easy, he failed in his first attempt in this case

78 *Tuberculin Treatment of Surgical Tuberculosis in Children C Förster
79 The Suction Mask (Bemerkungen zu der Arbeit Berlins in Heft 3 Band *XXIII über Erfahrungen mit der Saugmaske.*) F Kuhn
80 *Blood Borne Dissemination of Tuberculosis (Die hämatogene Verbreitung der Tuberkulose und die Disposition bei Tuberkulose) Wolff
81 Tuberculosis of Biliary Ducts (Sind die Gallengangstuberkel in der Leber das Resultat einer Ausscheidungstuberkulose?) M Lichtenstein
82 Sanatoriums for Tuberculosis Not a Source of Danger for the Environment (Die Tuberkulose Sterblichkeit unter der einheimischen Bevölkerung von Davos) J Gwerder
83 *Analogy Between the Blotting Paper Test for Diluted Acids and the Tuberculin Skin Reaction (Die Uebereinstimmung zwischen dem Verhalten verdünnter Säuren in Löschpapier und der Tuberkulinreaktion *in der Haut*) I Holmgren
84 *Bronchiectasia (Heilstättenerfahrungen über Bronchiektasien) F A. Bauer

78 **Tuberculin Treatment in Surgical Tuberculosis in Children.**—Förster regards the ideal technic as that with which a mild puncture hole and *local reaction is induced* without a distinct general reaction He reports the details of twenty one cases of tuberculous processes in bones or joints in children given a course of tuberculin treatment by this method No benefit was apparent in three cases but in all the others marked improvement resulted which he ascribes in large part to the tuberculin rounding out the ordinary general course of treatment. *He thinks that surgical tuberculosis in children is* an especially fine field for tuberculin therapy With symptoms of "scrofula," the dosage should be guarded with particular care not to permit a harmful reaction, Sahli's method is the *safest in these cases As children with surgical tuberculosis* are exceptionally susceptible to tuberculin, the average dose at first should not be over one or half a millionth of a *milligram* With this dose the puncture hole and local reaction is mild and just what is needed while the minimal general reaction does no harm The children were kept in bed and the anal temperature taken every two hours The dose was not increased until there ceased to be any reaction at the point where the needle had been introduced In case of a reaction, *another dose was not injected until all signs of the reaction* had disappeared, and then half the preceding dose was given When no further reaction was noticed, the dose was increased The blood findings under treatment are tabulated from seven cases Förster uses much smaller doses than others, and he thinks that this is one secret of his success The best results were invariably attained in the cases in which there had been the liveliest reaction to the Pirquet cutaneous tuberculin test

80 **Blood-Borne Distribution of Tuberculosis**—Wolff reviews experiences which confirm the fact that tuberculosis is disseminated within the body by means of the blood The bacilli in the blood stream settle where *an organ offers lessened resistance* by some predisposing elements or defective functioning These anatomic and functional deviations from the normal may be inherited or acquired The apices of the lungs offer a peculiarly favorable point for the settling of the bacilli

83 **Blotting-Paper Test for Acids and the Tuberculin Reactions**—Holmgren's test for gastric acidity by the way the fluid spreads when it is dropped on blotting paper was described in The Journal, March 18, 1911, p 857 He here *calls attention to the resemblance between the aspect of the* Pirquet skin tuberculin test and the phenomena of adsorption on blotting paper, especially the separation into two concentric zones He describes the formulas to express the conditions, and tabulates the findings in large numbers of cases in which the Ellermann Erlandsen titration tuberculin test was applied The formula used to express the acidity in the blotting paper *test applies likewise to the skin tuberculin reaction* For titration test see The Journal, 1909, lii, 1634, and 1912, lix, 1326

84 **Bronchiectasia**—Bauer gives a detailed description of ten cases of bronchiectasia In each case the diagnosis had been pulmonary tuberculosis and the patients had been admitted to the sanatorium on this account. No benefit was derived in any instance from the sanatorium treatment Two of the patients were given operative treatment. The reclining chair *aggravated the cough and expectoration in two cases, the* best results were obtained by lowering the head (Quincke's *Hängelage*) and a course of pills of digitalis leaves and extract of belladonna, 0 3 gm. each, divided into thirty pills one or two a day being taken The treatment was thus such as can be carried on anywhere In all his cases the apices showed about the same findings and were free from autoch*thonous by sounds Conditions thus approximating normal in cases with such severe cough and difficulty in expectoration in young people should suggest the possibility of bronchiectasia* Another differential point is the contrast between the slight percussion findings and the extremely irregular auscultation phenomena With scoliosis the convexity is on the most diseased side, probably from cicatricial shriveling He discusses *the connection between bronchiectasia and pulmonary* tuberculosis Circumscribed bronchiectasia is particularly important on account of its connection with trauma and tendency to hemorrhage In one of his cases the bronchiectasia had persisted in a latent stage for twenty five years, in another for over ten The bronchiectasia often dates from childhood and prophylaxis and early treatment are of great importance

93 Vaginal Operative Treatment for Uterine Hemorrhage Would Reduce Infant Mortality (Wie können jährlich 50 000 Kinder in Deutschland gerettet werden?) A Dührssen

85 **Trauma and Tabes.**—Schultze gives the details of three cases in which tabes had developed apparently immediately after a trauma but his investigations showed that it must have existed before the accident. The latter did not have even an aggravating effect on the tabes in two cases, in the third case the new symptoms of tabes that developed after the trauma were localized in the part that had been specially injured This case was further complicated by a traumatic neurosis There was no history of syphilis in any of the cases and the Wassermann test of the blood gave negative findings It is possible that the cerebrospinal fluid might have reacted positively, but Schultze always shrinks from applying lumbar puncture to persons after a trauma Nonne has also recently warned against puncturing "traumatikers." Schultze has witnessed disturbances develop in such cases after lumbar puncture which, in one instance, were more serious than the alleged consequences of the trauma The history of the cases illustrates anew the extreme readiness with which physicians as a rule are inclined to certify to a connection between an accident and a nervous affection The custom of waiting before summoning the medical specialist to ascertain whether the victim has a legal right to an indemnity in any event is very prejudicial to the ultimate welfare of the patient. In one of the above cases a specialist in nervous affections was not called in until five years after the accident. In a fourth case hemiplegia developed a few days after a fall into icy water, the symptoms suggesting a thrombotic obstruction in a cerebral vessel Gradual improvement followed during the next year but then symptoms of tabes became superposed on the hemiplegia The tabes was evidently an independent affection although all the disturbances probably had a common syphilitic basis

87 **Poisoning from Arsenic in Wall Paper**—The wall paper in question was in the sleeping room, and the symptoms of arsenic poisoning were abdominal pain and diarrhea with secondary anemia. As soon as the patients left home the symptoms improved, even without treatment, but recurred after an interval on their return home each time, and the assumption of poisoning from the wall paper was confirmed by tests of the paper In two of the six cases reported arsenic was found in the urine, no examination was made in the other cases The patients were two men and four women, all but two in the thirties The manifestations were of the intestinal catarrhal type in all, the possible persistence of such an intestinal trouble after removal of the wall paper need not invalidate the diagnosis, as complete recovery after chronic arsenic poisoning is rare In two of the cases the anemia was of the pernicious type One patient had not apparently suffered from the arsenic poisoning although occupying the same room two years before, she slept with the windows open then The intestinal catarrh did not develop until after she had been confined to the room for five weeks by a childbirth, the windows mostly closed Kuttner has found arsenic in cheap linoleums, and calls attention to arsenic poisoning from the floor coverings as possible explanation for certain puzzling cases of sickness

101 *Tests for Localizing Kidney Functioning (Ueber Nierenfunktionsprüfung) F Conzen
102 *Action of Radium Emanation on the Blood R von den Velden

101 **Testing the Kidney Function**—Schlayer and Takayasu have devised means of determining the anatomical location of the trouble in nephritis If 10 gm of a milk sugar solution is injected intravenously and takes more than five hours for elimination, it indicates diseased glomeruli When 0 5 gm potassium iodid is given by mouth and is not fully eliminated by the end of sixty hours, the tubules are involved Conzen in an examination of thirty seven patients found this method of great aid in diagnosing nephritis and the necropsy findings confirmed his diagnosis as to the seat of the lesion Intake of 10 gm of salt increases the albuminuria and leads to water retention and general malaise only in true nephritis and in severe congestion of the kidney In recent kidney affections particularly when the lesion is focal, the acidity and the amount of albumin run parallel, and the albumin decreases or disappears on the administration of sodium bicarbonate In other forms of nephritis there is no relation between the acidity and the amount of albumin in the urine

102 **Effect of Radium Emanation on the Blood**—Von den Velden states that the radium emanations were administered by inhalation, subcutaneous injection and by drinking water containing emanations. In every instance it was found to decrease the coagulation time of the blood One of the patients was a hemophiliac, and in this case the decrease was particularly noticeable.

113 Spray Method of Sterilizing Milk (Neues Verfahren zur Herstellung einwandfreier Trinkmilch) O Lobeck

105 **Improved Technic for Test for Occult Blood in the Stools**—Boas removes the blood from the meat given the patients for two or three days before applying the test for invisible blood in the stools He accomplishes this by pouring 100 gm of 3 per cent. hydrogen dioxid over 100 or 125 gm of scraped or chopped veal or chicken, stirring the whole up well as the foaming goes on The meat turns white and it is then rinsed on a fine sieve under running water for five or ten minutes until all the hydrogen dioxid is washed away The meat is then made up into hash balls Meat thus prepared will not interfere with the most sensitive tests for occult bleeding in the stomach or intestines This method is, of course, intended mostly for institutions, but intelligent patients can apply the procedure in their homes as a preliminary to the test It excludes all blood of foreign origin from the feces and thus does away with the necessity for refraining from meat and fish before the test In some cases the use of this meat or fish free from blood pigment may prove a useful in[illegible] for the benefit of therapeutic mea

112 **Industrial Po** [illegible] has f
blood test very useful in [illegible] l d

from lead, mercury, phosphorus, benzine and benzol In his experimental work, lead, mercury and phosphorus increase the resistance of the red corpuscles while benzine and benzol reduce it The Liebermann test is based on the laking of the reds in distilled water and the absence of laking in physiologic salt solution The unit is two minutes for the laking of one drop of undefibrinated blood, that is, 0 05 c c The blood is generally used for the test with a salt solution between 0 4 and 0 7 After two minutes salt solution is added of a concentration which brings the new solution to 1 per cent For example, to 5 c c of a 0 5 per cent solution is added 5 c c of a 1 5 per cent solution, thus bringing the concentration to 1 per cent The resistance quotient is the number of reds which fail to lake under these conditions in proportion to those which are dissolved

117 *Bacteria Involved in Diseases of the Respiratory Apparatus in Children II G Brückner W Gaehtgens and H Vogt

117 **Bacteriology of Respiration Diseases in Children**—In addition to eighty cases of lung affections reported by Brückner and his coworkers from the Strasburg children's clinic, the results of Holt's examination of over 500 patients are cited Influenza bacilli were present in the majority of cases and are undoubtedly of pathogenic significance Attention is called to the fact that in the years of influenza epidemics the mortality from pneumonia was correspondingly increased Though there is no absolute way of distinguishing influenza infections from infections with other bacilli, they seem to display a tendency to greater variations in temperature, a long course with remissions and exacerbations, and consecutive chronic conditions Recurrent bronchopneumonia and chronic bronchiectasia are a characteristic form of influenza bacillus infection Otitis media is also a frequent complication

Medizinische Klinik, Berlin

November 3 VIII No 44 pp 1769 1814

118 *Diagnosis of Miliary Tuberculosis M Matthes
119 *Pharmacology of the Sympathetic Nerve System H H Meyer
120 *Tuberculosis of the Eye (Erfahrungen und Gedanken über Tuberkulose und Tuberkulin) Heine Concluded in next number
121 Juvenile Paralysis M Rosenfeld
122 Percussion of the Apices of the Lungs in Tuberculosis T G Janowski
123 Vegetation and Civilization (Das mitteleuropäische Landschaftbild in seiner pflanzengeographischen Entwicklung) W Wangerin
124 Medical Department of the Turkish Army (Organisation des türkischen Kriegs-Sanitätsdienstes) E Franck

118 **Diagnosis of Miliary Tuberculosis**—Matthes remarks that the three types described in the text books, the typhoid, pulmonary and meningeal types, are frequently comb[illegible] blend into each other The meningeal symptoms [illegible] develop tardily in contrast to those accompanying [illegible] ordinary infections The diagnosis of miliary tubercul[illegible] is facilitated by discovery of some old tuberculous [illegible] focus or history of such Febrile urogenital or non tuberculous ear processes may simulate miliary tuberculosis [illegible] as in some recent cases of colon bacillus cystitis or [illegible]prostatic abscess In one case a woman with incipient [illegible] miliary tuberculosis aborted and the fever was ascribed to puerperal infection The fever may be low, and sometimes miliary tuberculosis develops without fever or without sweats Great irregularity of the fever is evidence in favor of miliary tuberculosis The heart findings are usually negative although there may be occasional accidental murmurs The pulse is never so soft and small as with sepsis Typhoid bacilli may be found in the blood when miliary tuberculosis attacks a bacillus carrier, and the agglutination test may be positive Matthes noticed in some of his cases great relative reduction of lymphocytes in the blood with a corresponding increase in the polynuclear cells If these findings are confirmed by others this polynucleosis may aid in differentiation On account of the fever, only the Pirquet tuberculin test is of any value, and this is unreliable in adults The livid, dusky face with the negative heart findings is instructive, as also dyspnea and a dry cough without expectoration There may be acute emphysema of the lung and the signs of bronchitis may be most pronounced above the upper lobes Instantaneous skiagrams may show bright pinhead spots, soft and sometimes confluent, very early in the disease The fluid obtained by lumbar puncture contains lymphocytes and more albumin than normal and, on standing, a fine network develops in it, in which tubercle bacilli may be found The pressure is generally above normal or may be subnormal He thinks it would be a good plan to examine the spinal fluid early in every case of febrile disease of obscure origin, even before meningeal symptoms develop The manifestations in the skin may be characteristic by the sloughing in the center of the punctate nodules, but tubercles on the choroid coat of the eye are the one unmistakable sign of the disease

119 **Action of Drugs on Vegetative Nervous System**—Meyer reports the results of his interesting research on the sympathetic system with epinephrin, nicotin, cholin, atropin, etc adding to the store of knowledge in regard to the different functions of these nerves and the localization of the functions

120 **Tuberculosis from the Ophthalmologic Standpoint**—Heine thinks that valuable information might be obtained from specialist examination of the eye under the influence of the tuberculin test He gives a colored plate showing the findings in twenty cases of tuberculosis or syphilis Examination of the eye with specialist equipment, he says, affords a better oversight of the progress of the case than examination of the lungs He has noticed a great difference in the prevalence of positive eye findings in different parts of Germany

125 **Formaldehyd Test for Uric Acid and Purin Bases.**—Schittenhelm gives the details for a technic which he says is a simple and reliable means to determine the proportion of uric acid in the urine It is based on the fact that the formaldehyd combinations of uric acid readily dissolve in water, while the uric acid and purin bases are very slightly soluble in water

127 **Chemotherapy of Cancer**—The research reported confirms the assumption that the action of the Roentgen rays and of radium depends mainly on the formation of cholin out of the elements of the lecithin, and consequently that cholin may have an elective action on cancer, alone or as an adjuvant to radiotherapy

128 **Color Test for Fat in Stool**—*Saathoff* uses a stain in addition to the heat method of distinguishing between the neutral fats, fat acids and soaps The best formula for the stain is 90 c c glacial acetic acid and 10 c.c. of 96 per cent.

alcohol, into which is stirred a knife point of Sudan III He discusses the importance of the findings in cases suggesting liver and pancreas disease, in metabolic disturbances and bowel trouble in infants, etc He found an abnormally large proportion of fat in the stools in patients with exophthalmic goiter and other thyroid derangement, and the course of the cases could be followed by the increase or decrease of the fat in the stools

129 **Mental Disease Cured by Gynecologic Operations**—Ortenau was amazed at Bossi's reports of the cure of chorea and hysteric paralysis by operative treatment of some lesion in the ovary or uterus (mentioned in The Journal Jan 6 1912, p 73 and elsewhere) He went to Genoa to Bossi's clinic to investigate the subject and reports what he saw there, giving the details of seven typical cases of mental disease entirely subsiding under needed gynecologic operative measures The large proportion of patients with mental disease in the gynecologic clinic was his first surprise, and then the rapid improvement under local measures This is particularly noticeable as the neurologists have long taught that the attention should not be attracted to the genital sphere in mental derangement In each case there was amenorrhea or dysmenorrhea connected with stenosis of the internal os or cervix, entailing infectious endometritis and dilatation of the uterus When these conditions were corrected the psychic disturbances subsided, even severe *mania* which had required isolation of the patient Bossi's plea is that restoration of normal conditions in regard to secretion and a proper outlet is liable to cure in many cases in which neurologic and psychiatric treatment alone is futile One patient presented the typical picture of dementia praecox, others severe melancholia and stupor The ages ranged from 22 to 41 The cases teach the necessity for gynecologic examination in every case of mental disease especially before committing any woman to an asylum Bossi insists that gynecologic examination should be a routine measure in every crime committed by a woman in the period just preceding or during the menses This would certainly, he declares, prevent many errors in justice which are now committed

130 **Diphtheria Bacilli in the Lungs**—Reye examined the lungs from sixty seven cadavers including forty three with recent diphtheria and twenty four after recovery from the diphtheria He found diphtheria bacilli in 85 per cent, in many cases the lungs were apparently entirely sound but the bacilli could be found up to the twentieth day after the onset of the diphtheria

131 **Polycythemia**—Jacobs adds two more to the thirty five cases of polycythemia on record with necropsy The essence of the disease is an increase in all the figured elements of the blood without apparent cause The data related suggest that the disease must be regarded as an abnormal proliferation of the blood elements and serum analogous to the proliferation of tissues in cancer The latter is a neoplasm of the solid tissue and the polycythemia is a neoplasm of the blood with consequent functional hypertrophy of the bone marrow

132 **Local Anesthesia in Operations on the Pharynx and Esophagus**—Hirschel describes the technic with which he blocked the glossopharyngeal nerve for removal of a cancer in the region in three cases, and the vagus for removal of a cancer in the upper part of the esophagus in another case

133 **Embolism After Injection of Bismuth Paste**—Brandes calls attention to the danger of embolism, reporting a fatality immediately following injection of bismuth paste into a fistula connected with an empyema left from pneumonia on the right side The catheter introduced into the fistula seems to have injured the wall at a bend, and the paste injected was thus forced into an adjoining vein whence it was carried into the venous circulation of the lung and, passing through the heart, the particles were scattered through the brain vessels and elsewhere through the body Alapy has reported a similar case but his patient recovered

134 **Prophylaxis of Gangrene of the Finger**—Fehsenfeld reports a case which confirms anew the great value of stimulating the capillary circulation by Noesske's method of cutting down to the bone at the tip of the finger parallel with the nail

135 **Local Treatment of Cancer**—Staudenmayer was quoted by Zeller as having had extensive experience with a 20 per cent arsenic mercuric paste in local treatment of cancer (See the Berlin Letter Sept 7 1912 p 815) He has had no recurrences in the cases in which a systematic course of this local treatment was given, and he never observed symptoms of poisoning Time will show whether Zeller's addition of silicic acid is an improvement He applied this local treatment only when an operation was refused or the patients were too advanced in years The paste does not pass through sound skin so the vicinity of the cancer or lupus patch must be freshened

138 **Destruction of Biliary Duct by a Gall Stone**—Riedel states that eighteen of his 695 gall stone patients had total or circular destruction of the cystic duct and two a partial side destructive process The common bile duct is more resistant he has only had two cases of perforation of the common bile duct among his 128 cases of stone in this duct The walls of the cystic duct are thin but it is very rare that a stone perforates into the open abdominal cavity, an abscess generally forms around the perforation or bulging duct and the common duct is thus secondarily involved The great danger from the opening in the cystic duct walls is that the flow of bile is less direct and consequently stones are not washed along in either the cystic or common duct

145 *Continuous Draining of Ascites (Zur Dauerdrainage bei Ascites) Osten
146 Shoulder Pain with Appendicitis (Schulterschmerz bei Appendicitis) Lochmann

143 **Acute Exophthalmic Goiter**—Schlesinger comments on the deceptive clinical picture sometimes presented by acute Basedow's disease, simulating cancer, lymph node tuberculosis or typhoid In his experience the patients came to the hospital with the diagnosis of hidden cancer The leading symptoms of exophthalmic goiter may be missing and the more uncommon symptoms predominant The most striking symptom is the rapid loss of weight, this is more rapidly extreme than even with cancer One such patient lost forty four pounds in a month, another sixty six pounds in ten weeks, and in a recent case the patient's weight dropped from 189 to 61 pounds —a loss of two thirds of her weight in eleven weeks Acute exophthalmic goiter should be suspected in every case of rapid loss of weight Another frequent symptom is enlargement of the spleen Fever is more common with the acute than with chronic Basedow In the acute cases the thyroid may be normal in appearance or even smaller than usual but auscultation reveals the vascular murmurs of true Basedow, soft, continuous, with rhythmic systolic accentuation or an arterial sibilant sound during the systole This rare type of systolic vascular murmur he has encountered only in elderly patients with Basedow A persistent retraction of the upper lid—Stellwag's sign—was observed very often and [illegible]ly and tachycardia was constant The [illegible] istic of Basedow but the arteries are [illegible] thin walls The blood chan[illegible] chronic exophthalmic [illegible] out cause or after [illegible] tite or none In three [illegible] tion were the only [illegible]

acute exophthalmic goiter Glycosuria is often observed also, the emaciation is sometimes ascribed to this alone Alimentary glycosuria could always be elicited in his cases, and the reaction was positive in the one case in which the alimentary galactosuria test was applied A correct diagnosis is particularly important as persons with acute exophthalmic goiter are exceptionally susceptible to external injurious influences, an insignificant operation, a brief general anesthesia or mild infection may prove fatal. Many such cases have been published and it is safe to assume that numbers of others have not been reported. One of his patients with acute exophthalmic goiter died suddenly a few hours after the onset of an ordinary follicular tonsillitis No cause for the sudden death could be discovered in another similar case He suggests that as hypoplasia seems to be a constant necropsy finding in such cases, the acute Basedow develops only when the injuries resulting from excessive or perverted thyroid secretion affect a hypoplastic individual In the absence of the tendency to hypoplasia, only the chronic form develops The more stormy onset of the acute form is the result of the lesser resisting powers of the hypoplastic The logical conclusion is that it is extremely dangerous to do an operation on persons with acute Basedow, every effort should be made to cure or at least to transform the acute into the chronic form Schlesinger keeps the patient in bed, preferably in the open air The food should be extra nourishing and digestible, avoiding sweets and much starch on account of the tendency to glycosuria Among the adjuvants he mentions Roentgen ray exposures, the advantage from which in these dangerous acute cases far outbalances the possible harm from the development of connective tissue rendering more difficult any operation on the thyroid later Very mild physical measures may also prove useful, including application of the continuous current to the neck

145 **Continuous Drainage of Ascites**—Osten has a patient who taps herself at need as she wears permanently a drain tube, clamped Except for nausea for a few days, there has been no disturbance from the drain during the three months it has been worn not even a local inflammatory reaction although the woman of 62 is a diabetic with cirrhosis of the liver The same technic might prove useful for an ovarian cyst in case operative measures are contra indicated

147 **Defective Development of Cartilage in the Fetus.**—From a study of a case of his own and those reported in the literature, Abels concludes that the cause of fetal chondrodystrophy is a disturbance of the internal secretions, in some cases of the thyroid, in others of the sexual glands There is in most cases an enlargement of the genitalia and in many cases an enlarged thyroid in the mother He cites one case of a woman who took thyroid extract during her pregnancy and gave birth to a chondrodystrophic fetus

149 **The Box Ward in the Vienna Pediatric Clinic**—Children are often admitted to general hospitals when already infected with some contagious disease To avoid the danger of house infection from such cases at the children's clinic in Vienna two series of six small glass walled rooms (boxes) were erected, each containing one bed Between the two rows of rooms is a corridor for the use of visitors and students The glass walls enable them to see the children without the possibility of transmitted infection Suspicious cases, or those developing sore throat, coryza or eruptions after admission are placed in these rooms They are not used for the more dangerous infections, such as cholera or small pox. They are easily disinfected so that they can be used again as soon as vacated, and there has been no instance of an infection being transmitted to the next occupant The children although thus scrupulously isolated can see all that is going on in the ward. The article is illustrated.

VISCERAL ORGANISMS *

ALEXIS CARREL, M D
NEW YORK

In previous articles[1] it was shown that connective tissue could be kept *in vitro* for several months in a condition of active life, and that a fragment of heart could pulsate normally for more than one hundred days after its extirpation from the animal, but the quantity of connective tissue maintained in permanent life was very small It would be important, for the study of many problems, to keep entire organs alive outside of the organism Therefore I attempted to develop a technic by which a system of organs could be caused to live *in vitro*

The method consisted of removing aseptically, *en masse*, heart, lungs, liver, stomach and part of the intestines, pancreas, adrenals, kidneys and spleen of an animal, a cat generally being used, and preserving these organs in an incubator at the temperature of 38 C (100 4 F), while the lungs were being artificially ventilated

The operation comprised five stages

1 A cat was etherized The skin of the anterior part of the neck, thorax and abdomen was sterilized Then the esophagus was ligated and severed under aseptic technic The trachea was cut transversely and a glass tube inserted in its lumen A catheter was introduced into it as far as the bifurcation, according to the Meltzer and Auer method

2 The abdomen was opened The aorta and vena cava were tied and cut in the lower part of the abdomen The small intestine was cut under aseptic technic The ureters were severed Then the aorta and vena cava were isolated from the posterior walls of the abdomen and their posterior branches tied The peritoneum surrounding the kidney was dissected The splanchnic nerves were cut Then the abdominal viscera were wrapped in a Japanese silk towel, thus being completely separated from the abdominal wall They remained united to the animal by the aorta and vena cava

3 The thoracic cavity was opened and the mammary vessels were clamped Then the thorax was severed longitudinally, and the diaphragm completely separated from the thoracic wall Artificial respiration was established The anonymous arteries were tied, and the animal died The superior vena cava and the azygos vein were tied and cut The vagus, sympathetic and phrenic nerves were severed All the posterior branches of the thoracic aorta were cut Generally the heart pulsated weakly and the blood-pressure was very low

4 Then the thoracic and abdominal viscera, united through their blood-vessels, were removed from the cadaver of the animal, and placed in a tray containing Ringer's solution, at about 38 C Ordinarily the heart still pulsated slowly and regularly But the blood-pressure was very low, the arterial pulsations weak and the appearance of the organs very anemic A careful hemostasis of the small vessels was made After a few minutes the blood-pressure rose and, in a few cases, became almost normal Generally a blood transfusion was made from the carotid artery of another cat to the inferior vena cava of the visceral organism Then the lungs became pink the blood-pressure was higher than normal and the heart was beating strongly from 120 to 150 per minute The abdominal aorta pulsated violently and strong pulsations could be seen in the arteries of the stomach, liver and kidneys Peristaltic contractions of the stomach and of the intestines were observed If a few minutes after the transfusion, the pressure was still above normal, a quantity of blood was allowed to flow from the lower part of the abdominal aorta Then, the appearance of the viscera was the same as the viscera of a normal animal

5 The visceral organism was placed in a tin box filled with Ringer's solution, covered with thin Japanese silk and protected by a glass cover The tracheal tube and the esophageal tubes were fastened to proper openings in the anterior wall of the box Artificial respiration was carried on by a continuous current of air interrupted ten times per minute Dr Meltzer kindly examined the respiratory conditions in these experiments, *showing me a method for obtaining a proper ventilation* of the lungs He has contributed, in a large measure, to the rapid success of these experiments Water or food could be injected into the stomach through the esophageal tube The intestine was pulled through a glass and rubber tube fixed through the posterior wall of the box The end of the intestine was fixed by a circular suture to the edge of the rubber tube, an artificial anus being made The box was then put into an incubator at a constant temperature of about 38 C

It was then observed that the viscera were living in an apparently normal condition The pulsations of the heart and the circulation of the organs were normal The intestine emptied itself through the artificial anus by regular peristaltic contractions When the intestine was empty, bile and intestinal juices were evacuated In an experiment in which the stomach was full of meat at the time of death, normal digestion occurred After five or six hours, hyperemia of the peritoneum of the intestine appeared It seemed as though peritonitis developed progressively and in some cases the intestine was paralyzed Nevertheless, the circulation remained excellent and a section of a small mesenteric artery produced an abundant hemorrhage.

---

* From the Laboratories of the Rockefeller Institute for Medical Research

[1] Carrel Alexis Rejuvenation of Cultures of Tissues The Journal A M A Nov 11 1911 p 1611 Jour Exper Med 1912 xv, 516 Pozzi, C R Bull de l Acad. de méd Paris, June 1912

Some of the visceral organisms died almost suddenly after three or four hours, but most of them were still in normal condition ten hours and even twelve and thirteen hours after the death of the animal to which the organs belonged. The death of the visceral organism was announced by some irregularities in the pulsations of the heart, which were also weaker. Then the heart stopped suddenly.

In the last experiment the death of the visceral organism occurred thirteen hours and fifteen minutes after the death of the cat from which it originated. It is probable that the duration of life will be increased by certain modifications of the technic, but, as it is, a visceral organism can profitably be used for the study of many physiologic and chemical problems.

Sixty Sixth Street and Avenue A.

A STUDY OF THE CAUSES OF DEATH IN ONE HUNDRED PATIENTS WITH HIGH BLOOD-PRESSURE *

THEODORE C. JANEWAY, M.D.
NEW YORK CITY

In a study of the subsequent histories of some 500 persons showing a systolic blood-pressure of 170 or over, seen in my consulting practice or in that of my father during the past eight years, it was found that approximately 150 patients were known to have died. For 100 of these, accurate information as to the date of death, the exact cause of death, and the important later symptoms was obtained. The latter data I owe largely to the prompt and cordial cooperation of the family physicians of these patients in answering my somewhat numerous inquiries, and I desire here to express my appreciation of their assistance. A study of this character, of an essentially chronic group of diseases, is possible only in private practice among patients of the intelligent classes; it is impossible with any hospital material, however large. Many of the problems regarding the causation and development of the so-called degenerative diseases of later life are to-day a fruitful field for truly scientific investigation by the general practitioner.

From the very nature of the investigation, the exact determination of the primary disease underlying the state of high arterial pressure in each case is impossible, and the clinical diagnosis must be a matter of personal opinion based on a consideration of all the symptoms and signs during life. An ideal study would include a complete autopsy of each case, but for the purposes I had in view, 100 cases of hypertension followed from the first symptom to death, with notes of my personal observations are of more value than a like number of hospital autopsies. My personal impression, gained in part from such a hospital experience of a one-sided kind, the patients being of the lowest social class, has always been that the most frequent mode of death in chronic nephritis is by gradual cardiac insufficiency. My desire to obtain exact information on this point among the well-to do and further to determine, if possible, whether the initial symptom or the prominent early symptoms associated with high blood-pressure are indicative of the probable death to be expected and, therefore, to be guarded against, was my motive in undertaking the analysis. It is clear from the character of the material studied that the less chronic and more progressive types of nephritis associated with marked general edema will be inconspicuous as contrasted with their frequency in a hospital service.

CLASSIFICATION BY CLINICAL DIAGNOSES

My clinical diagnoses of the primary underlying diseases of 100 patients were as follows:

Chronic nephritis (*no attempt to differentiate anatomic types*)	79
Diabetes	7
General arteriosclerosis	4
Coronary sclerosis	4
Aortic regurgitation (possibly syphilitic aortitis)	2
Aortic aneurysm (probable)	1
Primary myocardial disease	1
Paroxysmal tachycardia (with secondary myocardial insufficiency)	1
Hypertension without nephritis, evident arteriosclerosis, or cardiac disease	1
Total	100

In all the cases of diabetes, chronic nephritis or some manifestation of arterial disease had supervened on a preexisting diabetes. This, of course, is common, and the figure is almost identical with my statistics of four deaths from chronic nephritis among fifty fatal cases of diabetes observed within the same period. Out of 220 diabetics, again, fifty showed high blood-pressure—another evidence of the frequent association of cardiovascular and renal disease with diabetes in elderly individuals. In the younger patients with pure diabetes, terminating so frequently in coma, high blood-pressure is not observed; diabetes, therefore, stands in no direct causal relation to the high blood-pressure, but in individuals past middle life it seems to predispose to the development of those changes which produce hypertension. Elliott has reported similar findings, which contradict the idea of Potain that diabetes is a hypertensive disease.

In the entire series, pericarditis was definitely diagnosticated once and suspected only one other time. Since pericarditis is found at autopsy in such patients distinctly more frequently than this it is highly probable that it was overlooked. Of the four cases of arteriosclerosis without proof of nephritis in one there was a pressure of 170, and in the other three it was over 200. It is possible that these patients had contracted kidneys, for as a rule general arteriosclerosis is unassociated with increased blood-pressure. On the other hand many of the younger individuals in this group with evidences of severe chronic nephritis showed the most extensive and extreme peripheral arteriosclerosis. Of the five patients below 40 years of age, however, only two men, respectively 32 and 36 years old, had arterial thickening, but in them it was extreme. In the non-fatal cases of the larger group of 500 are a number of patients in whom high blood-pressure and associated cardiac hypertrophy are the only objective evidences of disease. The latter are largely women. The single similar case in this series of deaths was a woman, aged 74, who had had high blood-pressure for six years, associated only with neuralgic pains and mental depression. Her pressure ranged between 190 and 200. She died of pneumonia, having developed some symptoms of failing heart during the months preceding her death.

---

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-Third Annual Session, held at Atlantic City, June, 1912.

SEX AND AGE INCIDENCE

Among 100 cases, 74 were men, 26 women Of the women, 22 were or had been married and four were single

The ages at death were known in 114 cases They ranged as follows

Below 20 years,	2 cases, about	2 per cent
20 29 years,	0 cases, about	0 per cent
30 39 years,	3 cases, about	3 per cent
40 49 years,	24 cases, about	21 per cent
50 59 years,	39 cases, about	34 per cent
60 69 years,	32 cases, about	28 per cent
70 and over,	14 cases, about	12 per cent
	114	

The youngest patient in the group was 16 years old, the disease following two years after a mild scarlet fever The oldest patient was a man of 80, in whom arteriosclerosis and retention from a hypertrophied prostate seemed to be causative factors

ETIOLOGY

I have not attempted a study of the etiologic factors, since I propose to do this for the whole group of 500 cases One fact of interest may, however, be mentioned here In only one of the twenty-six women did chronic nephritis originate during pregnancy The group includes another case of great etiologic interest—that of a physician of 44 who, while attending a confinement case in the country, was obliged to spend forty-eight hours in a freshly painted room He developed lead colic immediately and after two weeks lead neuritis, which was progressive, and he came to me on account of this His urine had been found normal in a life-insurance examination made just previous to his illness, albumin appeared a month after the wrist-drop, and I saw him at the end of one year He then showed extensive muscular atrophy, hypertrophied heart with accentuated aortic second sound, a systolic blood-pressure of 180 and very slight arteriosclerosis, the specific gravity of the urine was 1 012, with a large amount of albumin and a few hyaline casts The lead line was still visible on the gums His red cells showed marked granular degeneration One week after my examination he went into sudden coma and died in thirty-six hours

CLASSIFICATION OF 100 CASES BY CAUSES OF DEATH

Of the 100 cases, the immediate causes of death were as follows

Gradual cardiac insufficiency	29
Uremic convulsions or sudden coma	15
Chronic uremia	20
Uremic psychosis	1
Cerebral apoplexy	14
Acute edema of the lungs	4
Angina pectoris	3
Sudden death (unclassified)	4
Progressive anemia	2
Acute pneumonia	4
Unrelated diseases	4
	100

In the above classification I have attempted to determine what was the most important cause of the fatal issue Very frequently, cardiac insufficiency was followed by acute or chronic uremia, or was accompanied by anemia in a few cases, but in all such instances the death was recorded as due to cardiac insufficiency Similarly, when uremic convulsions supervened on a chronic uremic state, the death was credited to the latter When, however, cardiac failure developed during a terminal uremic state, death was held to be by chronic uremia It is quite possible that the fifteen cases of more acute uremic manifestations include a number in which autopsy would have shown apoplexy as the real cause Under acute edema of the lungs I have classed only cases of those patients who died of sudden suffocative pulmonary edema, without marked symptoms of preceding heart weakness In addition to the three patients who died of anginal attacks, a fourth was characterized throughout by equally severe attacks which persisted until the day of death, but the fatal issue was brought about by gradual heart failure with anasarca and dropsical effusions Four patients developed severe anemia, of these, one died of uremic convulsions and one of gradual heart failure

Of the other two in whom death was due to anemia and exhaustion, one was a girl of 19 who had had acute nephritis during diphtheria at 9 The original attack was characterized by profuse hematuria There were frequent recurrences of hematuria, with fever, scanty urine, headaches, gastro-intestinal disturbances, edema of nephritic type, and, after menstruation was established, increasingly severe uterine hemorrhages When seen four months before death she showed a double aortic murmur, with a greatly hypertrophied heart, a blood-pressure of 200 systolic, 125 diastolic, low-gravity urine with a large amount of albumin, and loaded with granular and hyaline casts The eye-grounds showed old hemorrhages In this case a hemorrhagic tendency seemed to be manifest throughout There was no history of a "bleeder" family, so that the tendency must have been associated with the nephritis and endocarditis There was no evidence of bacterial endocarditis, but no blood-cultures were made

The other patient dying of anemia is a striking example of a type which I think is frequently overlooked, though unquestionably rare She was a widow, aged 55, with a strong family history of cardiovascular disease Six and one-half years before her death she had had a supposed "nervous prostration," one year later she had an attack of dizziness and aphasia lasting one hour From then until one year before death her blood-pressure ranged between 210 and 230 systolic, with a moderately hypertrophied heart, an aortic systolic murmur and moderate arteriosclerosis The urine was always normal in quantity and specific gravity, with an occasional trace of albumin and a few casts until the last two years, when the specific gravity fell The only symptoms were lassitude and slight dyspnea on exertion Eight months before death she developed nausea and anorexia which became extreme, with attacks of sore mouth and of diarrhea after eating She showed complete achylia and an increasing secondary anemia She gradually became emaciated, becoming more and more sallow and weak, and her blood-pressure fell to about 170, where it remained until death She died of anemia and inanition At no time was the blood morphology that of pernicious anemia, and there was no evidence at all of carcinoma This type of death, by progressive anemia, occurs from time to time, and at autopsy only unsuspected contracted kidneys are found to account for it

The uremic psychosis occurred in a man of 60, with a history of recurring gout for [illegible] ars and evident chronic nephritis with a bl[illegible] f 200, hypertrophied heart and mod[illegible] had no symptoms until five mo[illegible] to show loss of control [illegible] death, following a [illegible] active delirium with delusions, constant incoherent talk, and complete disorientation, without much restlessness and no twitching or other usual uremic symptoms He died in this state Whether the condition was one of rapid organic dementia or of uremic insanity it is difficult to determine

RELATION OF LENGTH OF ILLNESS, INITIAL SYMPTOM AND PROMINENT EARLY SYMPTOMS TO CAUSES OF DEATH

A computation of the duration from the earliest recorded symptoms which could be associated with high blood-pressure or chronic nephritis to death, in all those cases in which it was possible, showed no striking differences between the various groups (Table 1)

TABLE 1—DURATION OF ILLNESS IN RELATION TO CAUSES OF DEATH

Causes of Death	Cases	Duration Average Yrs	Average Mos	Longest Yrs	Shortest Yrs	Shortest Mos
Cardiac insufficiency	26	3	10	10		4
Acute uremia	14	3		8		5
Chronic uremia	21	3	1	7		4
Cerebral apoplexy	14	4	6	11		11
Angina pectoris	3	4	3	6	3	6
Acute edema of lungs	4	3		4	1	8

A careful classification of the cases grouped under each cause of death with reference to the initial symptoms did not show much of importance, as the initial symptom in many cases was not readily related to the time of development of the high blood-pressure or of the evidences of nephritis A somewhat larger proportion of the patients who died of cardiac insufficiency (twelve out of twenty-nine) began with dyspnea on exertion, as contrasted with the other groups Two of the patients who died of acute uremia, five of those of chronic uremia, and two of those of apoplexy began with headaches, whereas only one of the much larger group of cardiac insufficiency did so Paroxysmal dyspnea was the initial symptom in five patients dying of cardiac insufficiency and in one that died of edema of the lungs, but in no others Polyuria as an initial symptom was noted by three of the patients dying of chronic uremia, two dying of apoplexy, and one dying of heart failure Neuralgic pains and neurasthenic symptoms, physical or mental, came first in a few cases Loss of flesh, nose-bleed, hemoptysis, and gastro-intestinal disturbances occurred in a still smaller number

The entire 100 cases have been tabulated under the prominent early symptoms, and simultaneously subdivided into the groups already given under causes of death (Table 2)

TABLE 2—THE RELATION OF PROMINENT EARLY SYMPTOMS WITH HIGH BLOOD-PRESSURE TO CAUSES OF DEATH

Symptoms: Dyspnea on Exertion	Paroxysmal Dyspnea	Edema of Lungs	Anginoid Pain	Edema of Legs	Polyuria	Headache	Visual Disturbances	Hemiplegic Attacks	Loss of Flesh	Neurasthenic Symptoms	Causes of Death	No of Deaths
24	13	1	5	7	8	1	1	2	2	1	Gradual cardiac insufficiency	29
7	2	0	1	0	7	2	1	2	3	3	Uremic convulsions or sudden coma	17
5	1	2	3	0	11	8	5	4	5	1	Gradual uremia	20
6	2	0	2	2	2	2	1	4	0	4	Cerebral apoplexy or its results.	14
1	1	0	2	0	0	0	0	0	0	0	Angina pectoris	3
2	2	1	1	1	1	0	0	0	1	1	Edema of the lungs	4
3	3	0	1	1	3	2	0	1	3	6	Other causes	13
48	24	4	15	11	32	15	8	13	14	16		100

Several facts of real significance for prognosis appear from a study of these symptoms which, as I have indicated by the double line in the table, seem to fall roughly into two classes, the first rather definitely cardiac symptoms and the second symptoms which must be interpreted either as toxic or as due to localized vascular disease in the brain Out of forty-eight patients showing dyspnea on exertion as a prominent early symptom, twenty-four died of cardiac insufficiency, or, from the other standpoint, of twenty-nine patients dying of cardiac insufficiency, twenty-four complained of definite dyspnea on exertion early in their disease This proportion is higher than that found in any other group The same relation holds good for paroxysmal dyspnea, thirteen of the twenty-four patients exhibiting this symptom also died a cardiac death In this group one also sees that two of the four patients who died of edema of the lungs had attacks of sudden dyspnea, and one other had attacks of recurring edema of the lungs Fifteen patients had early anginoid pain on exertion, only two of these died of angina Of eleven patients showing edema of the legs in the early stages of illness, seven died of insufficient hearts, none of uremia

On the other hand, out of thirty-two patients who noted polyuria or nocturnal frequency of urination at the beginning of their illness, eleven died of chronic and seven of acute uremia, while only eight died of insufficient hearts, though this was a much more frequent cause of death for the whole group The relationship of certain forms of headache and subsequent uremia is equally striking Eight out of fifteen patients complaining of headache died of chronic uremia, two of acute uremia, two of apoplexy and only one of heart failure The distinctive early-morning headache of nephritis, passing off toward noon, or intense and persistent headache, seemed to be the types associated with the most serious outlook Many of these patients suffered from past migraine, which was not considered in making these tabulations Migraine, of course, has no such prognostic significance The majority of these patients recognized the change in the character of their headaches

Early ocular symptoms also appeared preponderantly in those patients who died of chronic uremia (five out of eight in all) Early hemiplegic attacks occurred thirteen times, four times in patients who afterwards succumbed to apoplexy Of the others, four died of chronic and two of acute uremia, two of insufficient hearts, and one of anemia An early uremic convulsion was noted once in the cardiac group and once in each uremic group Marked loss of flesh occurred fourteen times, and five of these patients died of chronic uremia

So far, then, as conclusions may be justified from a study of a group of one hundred cases so selected, the following seem reasonable

1 The early occurrence of dyspnea, whether on effort or of the paroxysmal type, in a patient with high blood-pressure indicates marked danger of cardiac insufficiency In such patients the disease must be treated as a cardiac disease, especially by safeguarding methods

2 Anginoid pain, even when of marked severity, occurring on exertion in persons with high blood-pressure, does not make the prognosis worse than do other cardiac symptoms Of course, every precaution must be taken to prevent overexertion The majority of these patients will not die in an anginal paroxysm

3 Complaint of polyuria, nocturnal frequency, marked headache, or of visual disturbances by a patient with high blood-pressure, especially if that patient be below 50 years of age, should make the prognosis very guarded, for uremia is a frequent mode of termination in such cases

ABSTRACT OF DISCUSSION

Dr L. F Barker, Baltimore I should like to emphasize, and just as strongly as has Dr Janeway, the relation of many of these cases with high arterial pressure to disease of the arteries themselves If you will recall the statistics given you will note that 75 per cent of the patients had chronic renal disease, 7 per cent had diabetes, 4 per cent had an evident arteriosclerosis and 4 per cent had coronary sclerosis It seems to me probable that many of the renal cases were really atherosclerotic in origin It is uncommon in these cases to find a high grade of arteriosclerosis of the palpable peripheral blood vessels Recent pathologic studies have revealed changes in the small arteries which supply the internal organs, especially the kidneys, brain and heart These cases we usually refer to as instances of chronic nephritis with high blood pressure In all probability most are due to arteriolar disease, not to disease of the larger arteries Indeed, one might be entirely misled by feeling the larger arteries Some of the cases were doubtless instances of chronic (diffuse) glomerulonephritis, as was the one referred to by Dr Janeway which followed scarlet fever

Streptococcus toxins can cause an acute inflammation of the glomeruli, which may go on to a chronic diffuse glomerulonephritis In the cases of hypertension that terminate fatally, myocardial insufficiency, with or without uremia, is a common end phenomenon Many of us fail in the treatment of these cases of chronic renal disease, cases with high blood pressure, because of our failure to direct the treatment more toward strengthening the heart muscle There should be enjoined rest in bed, a limited diet, cardiac tonics and digitalis (even with high blood pressure) as soon as signs of myocardial insufficiency set in

What I have just said leads me to sound a note of warning against the indiscriminate use of vasodilators in these conditions, and especially against the excessive use of nitroglycerin, the nitrites and allied drugs I think that more harm than good comes from the use of vasodilators in the cases we are now discussing Over and over again I have seen, as the result of reducing the blood pressure, a sudden collapse, the patient exhibiting anuria, dyspnea and signs of uremia Some of the patients can be saved, or could have been saved, by stiff doses of digitalis or strophanthus These patients must have a high blood pressure in order to give the organs a proper blood supply The patient is exposed to two great dangers that of too low blood pressure on the one hand and too high blood pressure on the other In rare instances with a very high blood pressure, one may cautiously attempt to reduce this pressure because of the danger of cerebral apoplexy, even here, as a rule, more is accomplished by rest, purgation and diet than by vasodilators

Dr Louis Faugeres Bishop, New York I believe that the treatment of arteriosclerosis and the proper understanding of it, and the advances in its treatment in our endeavors to help these patients, must be founded on pathologic physiology and chemistry and not on pathologic anatomy alone I believe that there are many cases due to chemical damage produced by amino-acid poisons in particular, an auto intoxication Dr Janeway has dwelt on the terminal cases What can we do for extreme cases? I do not do any work now in medicine except deal with patients with heart disease and arteriosclerosis I am sure that in at least three cases I have saved lives and restored the patients to a fair degree of safety by abstracting about 1 quart of blood by phlebotomy, followed by a regimen There is too much blood in the arteries and veins, an auto intoxication exists and apoplexy threatens, something must be done quickly in order that life may be saved In fact, these patients are often so well satisfied that they return and ask to have the operation repeated These are the very high blood pressure cases

I differ from most authorities regarding exercise in the treatment of these cases I am a firm believer in exercise The condition of the heart muscle, as Dr Barker has just said, is the key to the situation and the question arises, especially in cases of advanced arteriosclerosis, how we can improve the condition of the heart muscle and get it in good shape. I do not believe that we can improve the heart muscle by rest in bed Mackenzie and others tell us that the heart muscle fails in several ways If there is a failure in contractility, then the muscle should be given a rest, if there is a failure in its tonicity and general toxic condition, improvement follows on properly regulated exercise As a result of my experience with cardiac cases I believe that exercise is best for almost every heart case! I think that more patients die because of being kept in bed and quiet than from injudicious exercise The regulation of exercise is an art that is acquired by experience

It has been my practice for a number of years in attempting to get rid of the intoxication to give castor oil, a proteid diet and outdoor exercise The patients to whom I am referring are those that I have seen in private practice and not in my hospital work I always divide the cases into certain stages The first stage is the diet and castor oil stage As time goes on another stage is reached which I call the digitalis stage This is the stage of failing blood pressure, in which there is a tendency to a secondary low blood pressure and which means that the blood pressure which measures high is relatively low, 200 may be the proper blood pressure for some individuals who have carried 220 or even 250, but less than that is for them low pressure

Dr Edward E Cornwall, Brooklyn, N Y High blood pressure as a symptom does not ordinarily call for direct treatment, for it is mostly a conservative procedure The regular treatment of this symptom should consist, as far as possible, in the removal of the cause, and only exceptionally should symptomatic treatment by vasodilators be given The exceptional cases are those in which accidents to the cardiovascular apparatus are urgently threatened by the high blood pressure, and cases of coronary sclerosis with symptoms, the latter especially are benefited by nitroglycerin in sufficient doses In the great mass of cases of arteriosclerosis, toxemia and nephritis, arteriodilators do harm In these cases we have one means of reducing the blood pressure which is rational
and often exceedingly effective it is removal, as far as
possible or advisable, by ctive diet, of th
factor of putrefaction t which
prominently present in
pressure This is the
cases of cardiova
it is often rewarded
toms That intestin
capable of raising
apparent proof f
rise of blood pres

intravenous injection of a substance isolated by Beyer from putrid meat which has a chemical composition somewhat similar to that of epinephrin

Dr **M. Howard Fussell**, Philadelphia I protest against the remarks of Dr Bishop He says that cases of heart failure due to high blood pressure call for exercise and not for rest and I fear some of us will infer that he means that a patient with a failing heart from a high blood pressure should be placed at once on graduated exercise I have no doubt that we who treat so many of these cases are united in our opinion with regard to the care of these patients I do not doubt that Dr Bishop and I would treat any given case exactly alike I feel that the best thing to do first is to place these patients at rest, as a result of such rest there results promptly a fall in the blood pressure After a time there is instituted. and very necessarily, a graded exercise

Dr **Nathaniel Bowditch Potter**, New York Some years ago I found that patients with high blood pressure got better or worse according to what they were told of the figures, and I learned that too frequent blood pressure estimation, especially in private practice, depressed the patients, just as frequent urine examinations and the knowledge of the increase of albumin and casts

Dr. **Theodore C Janeway**, New York It seems to me quite probable, as Dr Barker has stated, that the underlying condition in many of these patients is disease of the small arteries Are there any others? I do not know The effect of treatment seems to make it clear that this entire group will be resolved into parts Two groups at least seem distinct, that consisting of patients who die with failing heart, and that consisting of patients who die of uremic manifestations Then again there is the patient with an intermittent high blood pressure. In some cases there is a return to the normal blood pressure and this may remain for years In these patients, anatomic lesions of the small arteries are unlikely

I should like to corroborate what Dr Barker and Dr Cornwall have said regarding limitations to the use of nitroglycerin and its applicability only in those cases in which sudden dangerous accidents occur In cases in which the coronary artery is threatened with complete obstruction, the good results may be from its local effects, opening up the paths that have been narrowed not from its lowering the general blood pressure One must not consider apoplexy in these patients due to rupture of a vessel by the high pressure From our autopsy experience we know that many who die of apoplexy, of hemiplegias, have thrombotic softening and not hemorrhage I am in accord with Dr Fussell as to Dr Bishop's remarks It should be remembered that there are many cases of severe myocardial insufficiency which require absolute rest When later we begin to order for those patients gradual exercise, it requires good judgment The use of the high frequency current has usually seemed to me a method of 'bleeding' the patient in the metaphorical sense I have seen patients just after treatment, whose pressures were said to be greatly reduced and my reading has been about what it was before There are probably occasional patients who are really benefited, and others in whom it acts as a psychotherapeutic measure If one lowers the blood pressure a considerable amount, as Dr Barker has said, the patient may develop anuria, failure of the capillary circulation through important organs and become seriously ill Not lowering the blood pressure but safeguarding the circulation, is the aim of treatment

---

Importance of a Rectal Examination—Before you make a diagnosis in any form of rectal rouble it is absolutely essential that you should make a thorough examination of the part I note that very often through so called motives of delicacy—though what that means I confess I do not know—doctors tell us that patients refuse examination and that therefore the doctor has had to treat the case under very disadvantageous circumstances But if you will take my advice you will not treat any rectal disease unless you are permitted to make a thorough and complete examination—Harrison Cripps in *Clin Jour*

DUODENAL MEDICATION OF IPECAC IN THE TREATMENT OF AMEBIC DYSENTERY *

HARVEY G BECK, M D
BALTIMORE

In East India and other oriental countries, ipecac has been regarded for a century or more as the great remedy for dysentery In Europe and America, treatment by ipecac had fallen into disuse until quite recent times, on account, first, of its emetic action, second, of the deterioration and adulteration of the drug, and third, of improper methods of administration The revival within the past decade of the use of this drug as a remedy for dysentery was largely due to Patrick Manson, whose extensive experience in the tropics thoroughly convinced him that it was an efficient remedy

Besides Manson, a number of other authorities attest the value of ipecac Notably among these are Woodhull Major Rhoades, Simon, Dock, Freund, Barker and others Woodhull[1] refers to it as the one remedy which, if properly used, is as conspicuous in dysentery as quinin is in the malarial fevers, and urges medical officers to use large doses of it in all types of amebic dysentery He further adds that he has not known the treatment to fail Major Rhoades, U S Army, regards ipecacuanha and quinin as the sovereign remedies, the former by the mouth, the later by the rectum, and maintains that, if properly administered, the drug will give brilliant results in the majority of cases If properly administered, it is considered by S K Simon almost a specific for amebic dysentery He asserts that the amebas vanish almost at once

It may be interesting to note that our present attitude toward the ipecac treatment of dysentery is very much the same as it was 150 years ago The following quotation from the United States Dispensatory, 1854, will serve to illustrate

> John Helvetius, grandfather of the celebrated author of that name, having been associated with a merchant who had imported a large quantity of ipecacuanha, employed it as a secret remedy, and with so much success in dysentery and other bowel affections that general attention was attracted to it and the fortunate physician received from Louis XIV a large sum of money and public honors, on the sole condition that he should make the remedy public.

Sixty-five years ago the statement was made, in Watson's "Practice of Physic," that "subsequent to bleeding, the remedy from which the greatest benefit is derived is ipecacuanha " It has been repeatedly alleged that ipecac in small doses is a good prophylactic against liver abscess Indeed Calvert, professor of materia medica in the Calcutta Medical School, goes so far as to state that he believes ipecacuanha will cure hepatitis following dysentery, provided there is no suppuration In this connection it is interesting to note a statement made by Pilgrim,[2] superintendent of the Calcutta General Hospital

> In the past four years over 200 cases of dysentery have been treated and eighty two cases of hepatitis During the past three years since ipecac has been systematically employed not a single case of dysentery has been complicated by hepatitis while every case of hepatitis has recovered without suppurating The average number of operations for liver abscess has fallen from ten or twelve to three or four in the year

[2] Pilgrim Brit. Med. Jour 1910 ii, 2030

There is a diversity of opinion as to the proper method of administration, and yet, according to the experience of all who have employed ipecac, the proper method is insisted on Buchanan's[3] experience in Bengal has been very favorable in those cases in which he employed large doses Small doses, from 3 to 5 grains in pills, are utterly useless His directions are as follows [4]

> Castor oil should be given the night before, and, after the bowels have moved in the early morning, tincture of opium, followed in fifteen or twenty minutes by ipecacuanha in a dose of 25 or 30 grains The patient should lie undisturbed for four or five hours If vomiting occurs or if the stool has not much changed for the better within twenty four hours, ipecacuanha is to be repeated in half an hour

Woodhull employs a somewhat similar method, but uses counter-irritants over the epigastrium, such as iodin or mustard He says

> The stomach must be empty and the patient recumbent About twenty minutes before giving the ipecac, it would be well to paint the epigastrium with tincture of iodin, or apply a mild sinapism, though this may be omitted Ten or fifteen minims of tincture of opium may be given to be followed in ten or twelve minutes by 15 to 30 grains of ipecac Nothing should be given by the stomach for at least four hours and the recumbent posture should be strictly maintained If the first dose is rejected, it should be repeated after a short interval Ipecac controls capillary hemorrhage and before confirmed inflammation sets in, capillary leakage is the feature of dysentery, hence its favorable effects in this disease

Major Rhoades' method of treatment is as follows [5]

> The patient, having received his preliminary purge and all food and water having been proscribed for six hours, is given a hypodermic injection of morphin sulphate, ¼ grain (0 016 gm) to prevent vomiting At the same time an ice bag filled with finely cracked ice and protected with two thicknesses of gauze is placed over the pit of the stomach and another over the anterior surface of the neck The patient is directed to lie flat on his back, a third ice bag being substituted for a pillow and placed under the nape of the neck The patient is cautioned not to speak or move for four hours One-half hour after the morphin injection, the ipecacuanha is administered in eight to twelve pills of 5 grains each The patient is encouraged to resist by mental effort the desire to vomit and to try to sleep When the saliva begins to flow freely, he should be cautioned not to swallow it. Unless this is done, vomiting will almost certainly occur If vomiting does occur within an hour after administering the dose, it should be repeated when the stomach has become quieted After six hours a small glassful of iced ginger ale or a cup of tea is given, followed by frequent feedings of beef tea and albumin water late into the night The following morning, the dose of ipecacuanha is repeated and again on succeeding days until copious, pultaceous, brownish yellow stools appear and rapid amelioration of acute symptoms gives evidence that healing had set in This being the case, the dosage of the ipecacuanha is reduced to a 5 grain pill or capsule three times daily, and continued for about a week longer, the diet is increased, and at the same time lavage of the colon is begun

Patrick Manson[6] has still another means of administration

> The patient must abstain from food and drink for at least three hours Twenty drops of laudanum are then given, and a mustard poultice applied to the epigastrium About twenty minutes later, 20 to 30 grains of powdered ipecacuanha root, either in bolus or in a small quantity of water are administered The patient must then lie flat on his back without a pillow, and endeavor to avoid vomiting, he may neither eat, drink, speak nor move for three or four hours If vomiting occurs soon after the powder is given, in an hour or two a second dose may be administered After three or four hours, small quantities of food may be given during the succeeding six or eight hours, when the drug is to be repeated Guided by its effects, the use of ipecacuanha is kept up for two or three days A great drawback to this treatment is the severe vomiting which sometimes ensues, but, notwithstanding this drawback there can be no question of its value in some cases, although in others it appears to do little or no good If the ipecacuanha produces a large loose, bright yellow stool, improvement is nearly sure to follow

The action of ipecac on the ameba has not been definitely determined Vedder, U S Army, made some bacteriologic experiments[7] and showed that the *Bacillus dysenteriæ* was inhibited by a 2 per cent fluid extract of ipecac While the amebas in a 5 per cent bouillon culture were at all times killed by a fluid extract of ipecac in a dilution of 1/50,000, sometimes they were killed by a higher dilution of 1/200,000 Two varieties of amebas were used, but not *Entamœba coli* or *Entamœba dysenteriæ* He insists that ipecac containing the proper amount of emetin should be used and condemns its use in cases of the bacillary form of dysentery Dr H A Freund made some experiments with ipecac on the live amebas from the stools in the warm stage He concluded that it had a direct destructive action on the amebas and besides this effect it acts apparently as a cholagogue and sometimes as a purgative Under the treatment the ameboid motion of the parasites ceases in a few hours and disappears completely in two or three days

From this cursory review of the literature one is forcibly impressed with the fact that ipecac has a definite action on the amebas, and, if properly administered, is undoubtedly the best remedy at our command What is generally conceded, however, to be the proper method of administration proves such a formidable procedure that the treatment is wholly impracticable

In an attempt to overcome the many objectionable features of the methods in vogue, a simple, rational and more practical method has suggested itself to me, in the use of the Einhorn duodenal tube This tube was designed for duodenal aspiration and alimentation and it will be found an ideal instrument for the treatment of dysentery with ipecac For a complete description of the duodenal tube and the method of its introduction the reader is referred to the original article by Max Einhorn [8] As a rule patients have little difficulty in swallowing the tube and comparatively little discomfort afterward An examination of the stomach contents, to determine the presence of free hydrochloric acid, will help determine whether the tube has passed through the pylorus, which is done by aspirating a little of the fluid and testing with congo paper After each aspiration the tube is washed out with a little water and clamped When it has entered the duodenum, the aspiration is slower and more difficult and the fluid is alkaline and bile-stained Einhorn also recommends a milk test The patient is given a few swallows of milk and the stomach is then aspirated If milk is absent, the capsule is in the duodenum The time required for the capsule to pass into the duodenum varies from one to five or more hours

Ipecac is especially indicated in acute cases and in the exacerbations of the chronic forms It is said by some clinicians to have practically no effect in cases in which the symptoms are due to a mixed infection

In spite of the fact that all [illegible] were extremely chronic and refractory, [illegible] ng complicated with liver abscesses, the results were fairly striking, but the cases are reported more for the purpose of emphasizing the method than the results of treatment Powdered ipecac was employed either suspended in mucilage of acacia or macerated in plain warm water A 2-ounce metallic syringe was used to instil the remedy which represented from 1 to 2 drams of ipecac to the dose in a 6-ounce mixture Unquestionably much of the success of treatment depended on the quality of the drug Those cases which required more than three or four doses and in which the amebas reappeared in the stools were treated by a drug of an inferior quality On the other hand, the cases treated with a physiologically tested powder yielded after the first or second dose

CASE REPORTS

Case 1—*Patient*—J S, male, aged 64, janitor, ten years ago suffered from a liver abscess attributed to a wagon running over his abdomen He recovered from the operation, but never enjoyed good health Before the accident he suffered from mild attacks of dysentery and a few years after had an acute attack with bloody mucus in the stools and much tenesmus lasting several months No history could be obtained of the discovery of amebas in the stools or liver abscess

Examination—The patient showed marked pallor and emaciation and suffered from a moderately advanced pulmonary tuberculosis The abdomen was somewhat distended and coursed with large superficial veins There was an area of considerable resistance over the upper right rectus and tenderness along the border of the eighth and ninth ribs on the right side Owing to this tenderness, the liver could not be palpated He had a leukocytosis of 21,000 For several months he had a number of dysenteric stools each day which contained pus, blood and mucus A large number of active *Amœbæ coli* and yeast cells were found on examination of the stools

Treatment and Course—Patient was admitted to the Mercy Hospital Dec 12, 1910, was ordered a semisolid diet and salines followed by the administration of ipecac After the introduction of the tube the first dose (1½ drams) suspended in mucilage of acacia was administered No other discomfort than slight nausea ensued Examination the next day showed amebas in the stool, but these disappeared after an ipecac enema (ʒiv—Oi) Several days later the ipecac enema was repeated with the results negative for amebas Two weeks later ¼ dram of ipecac was administered duodenally followed by vomiting without expelling ipecac The following day a dram was administered, the results remaining negative for amebas The stools were examined at intervals of one or two weeks after the patient left the hospital and no amebas were found for six months, when a few, slightly motile appeared in the stools which averaged from two or three semisolid ones a day A month later, when amebas were again found 1¼ drams of ipecac was administered duodenally in my office No vomiting occurred The next day the patient had six or eight diarrheic stools, since then the stools have been better formed, there has been less abdominal tenderness and no amebas The patient was readmitted into the hospital in December, 1911, with alcoholic pneumonia, from which he died Previous to this illness, the stools were formed and free from amebas The pneumonia was associated with severe diarrhea, but careful examination of the stools failed to find amebas

Case 2—*Patient*—G S F, male, aged 32, soldier (referred by Dr F J Snyder, York, Pa), was admitted to Mercy Hospital March 28 1911 He contracted amebic dysentery while serving as a soldier in the Philippine Islands The disease began as a simple diarrhea, the number of stools varying from six to twelve daily After three months the stools were mixed with blood and pus and associated with great tenesmus At this time he was treated with ipecac and quinin according to the method of Major Rhodes In spite of the ice-bag applied to the back of the head and the spine, the mustard plaster to the epigastrium, the opiate internally and enforced quietude for hours before and after the administration of ipecac, the patient vomited after each dose Some improvement was noted after the treatment, but the symptoms soon returned From this time until 1907 he had been able to do light work, but since then became totally incapacitated

Examination—On admission to the hospital he presented an emaciated and anemic appearance with dull expression and sunken eyes The cervical and inguinal glands were slightly enlarged The abdomen was somewhat flattened and retracted, the recti muscles were tense and rigid and there was a marked tenderness over the whole abdomen There was no apparent enlargement of the liver or spleen The patient had a leukocytosis of 12,500 The stools averaged eight to ten daily, watery or semisolid in character, and contained mucus, pus and blood Active amebas were found in large numbers, as many as ten and twelve to the field

Treatment and Course—Patient was put to bed and on liquid diet Several high saline enemas were given Stomach contents showed free hydrochloric acid March 31, the duodenal tube was introduced at noon, a glass of milk and slice of bread were given at the same time

At 4 30 p m aspirated fluid was alkaline and bile tinged, then 1½ drams of ipecac in water were administered Slight nausea followed but no vomiting At 6 30 p m a second dose of 1¼ drams was given which caused some nausea and vomiting of mucus but no ipecac

Two days later the stools were well formed, passed without tenesmus and were free from blood and amebas A high enema consisting of ½ ounce of powdered ipecac with 10 minims of laudanum in a pint of water was given and retained for fifteen minutes This was repeated the next day On April 4, the fifth day of treatment, 1¼ drams of ipecac were administered duodenally and retained This was followed next day by another ipecac enema, which completed the treatment

The amebas disappeared from the stools after the first duodenal medication and colonic irrigation with ipecac The patient was in the hospital ten days A period of fourteen months has elapsed without treatment during which he has averaged one well formed stool each day, has gained in weight and strength and worked steadily Repeated examinations of stools have been negative for amebas

Case 3—*Patient*—W K, male, aged 35, soldier (treated through courtesy of Dr Craighill), was admitted to the University Hospital April 25, 1911 Patient had contracted amebic dysentery in 1907, while serving in the Philippines Symptoms were very acute from the beginning, averaging from thirty to forty stools a day, each containing blood and mucus He lost about 50 pounds during the first month of illness For the first two years following the attack he averaged from fifteen to twenty stools a day and more recently from seven to eight Early in the attack, yellowish brown pigmentation of the skin developed There was no nausea or vomiting but much pain and soreness in the abdomen Shortly before admission to the hospital he developed a cough and night sweats

Examination—The patient was extremely septic He was *emaciated, cachectic and slightly* jaundiced, with puffiness under the eyes The liver was enlarged and painful on pressure but there was no fluctuation The stools were thin, watery, yellow in color and contained mucus, blood and *Amœbæ coli* Numerous leukocyte counts showed a fluctuating leukocytosis from 8,000 to 11,200 The hemoglobin was 40 per cent Gastric analysis revealed the presence of hydrochloric acid with a total acidity of 26

Treatment and Course—April 30, 1911, at 8 30 a. m, the patient swallowed the duodenal tube without difficulty At 11 30 a m a dram of ipecac was administered The tube was left *in situ*, but the patient vomited some mucus containing a little ipecac about half an hour later, which caused the tube to be partly expelled One *fourth grain of morphin* was given hypodermically and at 4 30 p m a second dram of ipecac was given This was also followed by vomiting of *mucus and a little* ipecac A slight depression followed as an effect of the drug The following day an enema contain ing 2 drams of ipecac with 20 minims of laudanum in a pint of water was given This was repeated the next day, and the following day at 3 30 p m a dram of ipecac was administered duodenally followed in a few hours by another dram, which caused nausea and vomiting Another ipecac enema was given the next day when, owing to the condition of the patient, it was considered inadvisable to continue treatment

CASE 4 —*Patient* —G L, male, aged 62, soldier, contracted dysentery while serving in the army at Fortress Monroe in 1888 The disease persisted with great severity until 1893, after which the symptoms abated and the disease ran a milder course until 1901 During this year two liver abscesses developed, both of which were relieved by operation The following year an acute exacerbation occurred which was temporarily relieved by quinin irrigation Since then he had suffered more or less continuously until his admission to the hospital Sept. 6, 1911

Examination —The patient was sallow, cachectic and much emaciated He had marked abdominal tenderness but no enlargement of the liver He averaged twelve loose movements a day The stools were either liquid or semisolid, composed largely of pus, blood and mucus with numerous motile *Amœbæ coli*

Treatment and Course —Two days after his admission 2 drams of ipecac were administered through the duodenal tube in doses of 1 dram each, one hour apart No noticeable effects resulted from the first dose but after the second the patient complained of nausea which was followed in an hour by a chill and vomiting of mucus Two days later and after the third dose of ipecac the stools were examined but no amebas were found The third and fourth doses were followed by some discomfort and, in one instance a small quantity of clear fluid was vomited but no ipecac After the fourth administration a saline and an ipecac enema was given The stools remained watery but free from amebas and gradually decreased in number After the sixth administration of ipecac the treatment was discontinued The dysenteric symptoms persisted for several weeks without the appearance of amebas in the stools The stools then became well formed and have averaged one per day up to the time of his last report, eight months after treatment During this time no amebas have appeared in the stools and his health, twenty four years after contracting the disease, has been restored

CASE 5 —*Patient* —F C H female, aged 34, (referred by Dr Buxton) had good health until 1906, when dysentery set in, which persisted for five years During this time she averaged from ten to twelve dysenteric stools daily, usually accompanied with tenesmus Then followed a period of eight months during which she enjoyed fairly good health and averaged one well formed stool per day Four months before admission to Mercy Hospital the dysentery returned averaging four to five stools daily each containing blood and mucus and associated with abdominal pain and tenesmus

Examination —With the onset of this attack an abscess of the liver developed which ruptured into the lungs Since then the patient had had profuse anchovy sauce expectoration, averaging from half to one pint a day Repeated examinations failed to show the presence of amebas Tenderness was quite marked over the sigmoid On admission the temperature was 101 Blood showed an absolute leukocyte count of 17 900 Stools were thin and watery containing blood streaked mucus, many actively motile amebas and large numbers of *Cercomonas intestinalis*

Treatment and Course —On December 4, 1 dram of ipecac was administered without causing nausea, vomiting or other discomfort Three stools were voided the following day unattended by pain Amebas were found which were sluggishly motile No stool for the next forty hours The second dose of 1½ drams of ipecac, given December 7, caused slight nausea The following day the stool was fairly well formed and one motile ameba and numerous cercomonads were found The general condition of the patient showed improvement increased appetite, lowered pulse and temperature almost normal Stool examined December 10 was free from amebas and cercomonads

December 12, 2 drams of ipecac were administered This gave rise to considerable nausea and general abdominal pains which lasted about three hours Repeated examinations of stools for three weeks following showed an absence of amebas and cercomonads At the end of this time both amebas and cercomonads appeared in large numbers, but disappeared promptly after several ipecac enemas 2 drams to the pint

Patient was discharged with normal temperature and almost complete cessation of expectoration Stools were normal averaging one in twenty four hours The accompanying table shows the effect of treatment on the blood with special reference to leukocytes and differential counts

EFFECT OF IPECAC TREATMENT ON THE BLOOD WITH SPECIAL REFERENCE TO LEUKOCYTES AND DIFFERENTIAL COUNT IN A CASE OF AMEBIC DYSENTERY (CASE 5)

12/20			11 500	79	7	13	1	

CASE 6 —*Patient* —J P L, male, aged 30, traveling salesman (referred by Dr Bunting), contracted dysentery in 1906, while in New Orleans The symptoms came on abruptly as an acute attack with profuse dark watery stools The patient was treated in the hospital for seventeen days when the symptoms abated Since then he has suffered with frequent exacerbations increasing in severity until his admission to Mercy Hospital Dec 27 1911 For a year he had averaged daily from three to eight watery or semisolid stools, containing blood and mucus associated with marked tenesmus He had been treated with salol coated pills of ipecac in 1910 beginning with 50 grains a day the dose being reduced 5 grains daily for two weeks It was impossible to retain all of the ipecac as it caused vomiting and some of the pills were found in the stools undissolved Notwithstanding this fact the symptoms were temporarily relieved In June 1911 he was again treated with ipecac in keratin coated pills 30 grains a day, in addition to opium bismuth and tannic acid irrigation The ipecac was vomited either in the form of pills with the coating dissolved or disintegrated into a powder The symptoms were relieved for three or four weeks

Examination —Patient appeared slightly anemic, the lymph nodes of the neck and groin were enlarged and the abdominal wall was soft and relaxed with no rigidity or tenderness on pressure The liver and spleen were normal C [illegible] mission the stools were soft semisolid a [illegible] pus cells, active amebas and *T* [illegible]

Treatment and Course —After [illegible] gradually became thicker and [illegible] tion of the ipecac was followed by little or no discomfort and a gradual diminution of amebas and trichomonads Proctoscopic examination showed several healing ulcers in the rectum In this case treatment was discontinued for a while after three administrations of ipecac, but was resumed on return of symptoms, the results proving more successful The patient left the hospital two weeks after his readmission in fairly good health At his last report, he had continued to improve in general health, gaining strength and weight with no return of dysenteric symptoms, averaging one normal stool a day with no amebas

Case 7—*Patient*—F E H, male, aged 39, soldier, barber, (referred by Dr Rosenthal) had unimportant family and previous history Present condition began in 1900 while in the Philippines The first attack lasted eighteen days, stools averaged about six per day and contained blood and mucus The second attack occurred four months later Since then the patient has suffered with periodical exacerbations and had never enjoyed good health For the past two years his health was very much impaired He suffered with abdominal pains, two to six stools a day, frequent chills, fevers and sweats

Examination—Patient entered Mercy Hospital Jan 29, 1912 He was undernourished and anemic. He had marked flattening and relative immobility of lower part of right chest, probably due to an old pleurisy No râles were heard There was tenderness over the sigmoid, the liver was slightly enlarged and painful on deep pressure The lymph nodes were enlarged Leukocyte count was 13,150 Stools were watery, semisolid and contained blood and mucus with numerous amebas

Treatment and Course—He was given six doses of ipecac, 1 dram each, through the tube at intervals of three or four days, which caused some nausea and several attacks of reflex vomiting, but no ipecac was expelled The stools which after the first examination were loose and watery gradually became well formed No amebas were found after the first administration For ten days prior to his discharge from the hospital February 24, he averaged one normal movement daily Proctoscopic examination made during the course of treatment showed rapid healing of several ulcers located in the rectum Since leaving the hospital he has averaged one well formed stool a day with no further dysenteric symptoms Examination May 8, 1912, showed stools free from amebas

It appears from a study of these few cases that the ipecac treatment by duodenal administration is distinctly more efficacious than by other methods Many other forms of treatment had been employed without avail The fact that this series of most intractable cases were either permanently cured or relieved for a considerable period of time bespeaks efficiency of the method

Large duodenal doses of ipecac seem to have no injurious effects There are occasionally gastro-intestinal symptoms such as nausea, less frequently, vomiting and, rarely, diarrhea lasting from twenty to forty-eight hours Slight general depression may appear with a tendency to lowering of blood-pressure which rarely amounts to more than 10 mm even with doses as large as 2 drams The effect on the leukocyte count, as shown by the accompanying table, is a fair illustration of what occurred in most all of the cases

In conclusion I desire to acknowledge the valuable services rendered by Drs Charles E Simon and A W Skilton who examined the stools of my patients and Drs S H Hutchinson and J N O Connor for their clinical assistance in the study of the cases

Harmful Dusts—Another curious effect of dust has been observed in a form of temporary deafness among the workers in jute, from which twine and bags are made The fine dust of the jute fiber, mingled with the natural 'wax" of the ears, packs *into hard cakes against the tympanum*—W G Thompson in *Jour Maine Med Assn*

RECENT HYGIENIC IMPROVEMENTS IN DAIRYING*

RICHARD COLE NEWTON, M.D
Consulting Physician to the Mountainside Hospital Montclair N J., Member N J State Board of Health
MONTCLAIR, N J

The production of clean milk has engaged the attention of business men for only about a score of years, and while all recognize the necessity of great reforms in the production and handling of this substance, the means of accomplishing this desideratum on a large scale have hitherto seemed practically impossible, except at a cost to the consumer which has proved excessive to all but the well-to-do So many factors have had to be taken into account in the solution of this problem, that some of them up to this time either have been overlooked or have proved insurmountable The main factor has only recently begun to receive its due weight in sizing up the situation, and this factor is, as will be shown later on, the dairyman himself—not the man who sells the milk, but the man who produces it and packs it off to market

High-grade milk has for some years been brought to market from a relatively few high-grade and expensive dairies Some of this is called "certified" milk, and is produced under the most favorable possible conditions, and is sold for from 15 to 22 cents a quart, which, of course, is a high price for a poor man to pay So steps must be taken to produce a clean, safe milk which a poor man can afford to buy Of all the milk brought to market, not over 5 per cent can be "certified" while something must be done to make the remaining 95 per cent at least safe for the millions of poor babies whose main, or sole, food-supply is cow's milk

Years ago a friend of mine started a dairy farm in which he employed many new and expensive devices to render the milk as nearly perfect as milk can be made He employed maids, dressed like trained nurses, in clean starched caps and immaculate wash dresses, to do the milking, because he rightly maintained that women are gentler, neater and more dexterous at such work as milking than men, and that inasmuch as the moral treatment of the cow has an enormously important effect on the quality and wholesomeness of her milk, women, with their gentler and neater ways and more correct personal habits, are much better fitted than men of the same walk in life to milk cows and take care of the milk

He also invented a covered pail with a small opening in the cover and a diaphragm consisting of a cloth stretched over the opening, to be milked through Everybody was astonished at the great amount of dirt which collected on this sterilized cloth with each milking, no matter how many precautions had been taken in washing the milker's hands and the cow's flanks and teats Great progress was made in producing clean milk and the new barns, with their fancy fittings and concrete floors and bright airy stalls, were so crowded that some of the cows had to be kept and milked in one or two old dusty, ramshackle barns To the surprise of everybody concerned, the milk drawn in the old dusty barns was found to be nearly as clean and free from bacteria as that milked in the new up-to-date barns

You may ask how it was known so promptly that the milk from the old barns was so nearly equal to that produced in the new barns It was simply because the milk from every barn on the farm was carefully examined every day under the microscope and the bacteria counted This similarity in the milks produced under such diverse conditions was evidently due to the covered pail[1]

---

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association at the Sixty Third Annual Session held at Atlantic City, June 1912.

The fact that clean milk could by any means be produced in a dirty barn was a great discovery and bound to bring about radical changes in the entire dairy business Like many of the most important discoveries and inventions in the world, it came about largely through an accident Yet it is none the less valuable for all that, inasmuch as it bids fair to prove an inestimable boon to suffering humanity

The dairy farm of which I have just spoken failed financially, partly because it was started some years ago, before the public was so wide awake as it is now to the question of clean milk, and partly because the whole process of producing clean milk was then much more of an experiment than it is now

The man who started the dairy sold his interest in it after some years of struggle to make the public appreciate what he was offering them He made no money by his venture, but he came out of it with the idea firmly impressed on his mind that clean milk for the multitude can be produced and sold at a price within the reach of any man of moderate means, always provided that the farmer can be induced to cooperate with the milk company or the wholesaler who puts the milk on the market

I went with my scientific friend a number of times to a filthy and badly kept dairy and spent some hours of valuable time trying to impress on the dairyman how easy it would be to produce clean milk by a few simple precautions Patiently and carefully the doctor (for the scientific dairyman was primarily a doctor and a hygienist) would state and restate the steps to be taken and his listener would promise in a half-hearted way to carry out the directions, but would invariably wind up the discussion by asserting that he ought to get at least a half cent more a quart for his milk And so far as the farmer is concerned, this is the crux of the whole matter If he is to produce cleaner and better milk, he must have some reward for his extra pains and trouble and the higher degree of intelligence which he puts into his business The philanthropic attitude of those great milk companies which undertake to produce better and safer milk for the suffering and helpless babies of the tenements, and to pocket all of the advanced price themselves has not seemed to appeal to the farmer The farmer has had a hard enough time to make both ends meet without spending more money in producing wholesome milk than he can get for it As one of them has expressed himself, he feels sorry for the poor sick babies in New York City, but the babies he is most interested in and is bound to take care of are his own babies Consequently, if he should send better milk to market, he should demand a better price for it

One of the great milk companies has had a long and expensive litigation because the farmers from whom they purchased the milk which the company sold would not consent to have their herds tuberculin-tested The idea of offering any more money to the farmers for their extra expense and trouble in getting their herds tuberculin-tested never seems to have occurred to this company Now that the suit has gone against it, however, the company seems to have been able to make some arrangement with the farmers, inasmuch as it announces that it is prepared to furnish tuberculin-tested milk at 10 cents a quart to anyone who wants it

Now, in spite of every precaution that may be observed in drawing, handling and transporting milk, there is no absolute guarantee that it may not become contaminated with germs pathogenic to man

The epidemic of tonsillitis and influenza which prevailed in and about Boston last spring and summer and claimed many victims, of whom a considerable proportion died, was, after a careful and impartial investigation, traced to the milk from one of the best and most scientifically conducted dairies in the world It was also found that the contamination of the milk was not due to any fault or carelessness on the part of any employee or agent of that dairy So far as one can judge from a review of the testimony of the impartial and painstaking scientists who conducted the investigation, such a contamination of the milk of any dairy cannot be prevented by any means known to science, unless the milk shall be properly pasteurized or sterilized This episode in the history of scientific dairying has been dwelt on in this paper because it occurred so recently and was so thoroughly investigated Other similar occurrences have been reported from time to time in this country and abroad Some years ago I was interested in a study of the spread of a mild form of diphtheria by the milk of one of the best dairies anywhere, which is the pioneer "certified milk" dairy in America The investigation seemed to prove without question that the diphtheria was spread by the milk of this dairy, although every known precaution (except pasteurization) had been observed in preparing the milk for market

Mr Nathan Straus and many others, including the scientific man of whom I have been writing, agree with Professor Sedgwick and the other investigators of the Boston epidemic in asserting that milk cannot be guaranteed to be free from pathogenic germs (including those of tuberculosis) unless it has been pasteurized

Some physicians hold that pasteurized milk has lost some of its most valuable nutritive qualities, so that its constant use may produce rickety babies, and furthermore, that pasteurization may be a bad thing because by covering up nastiness in the milk, it will encourage lax and dirty methods in producing and transporting milk While it must be admitted that there is a certain amount of truth in these objections to pasteurization, those who favor the universal pasteurization of milk have, so far at least the better of the argument

While the matter was being discussed the other day our dairy doctor pointed to his own child, a ruddy and round little girl of 4, and said, "Do you see anything rickety about that child? She has never had any milk since she was weaned that has not been pasteurized and she has had very little other food of any kind And so far as the objection goes that pasteurization may be a cover for careless or dirty dairying no good dairyman will allow his milk to be dirty and trust to subsequent heating to conceal that dirt Even if he were disposed to do this the methods adopted by the milk company of which I am writ ich be presently described will effectua 1
fraud on the milk consumers
mind that milk must be past
guaranteed, the question how t

---

[1] The pail now in use does not have a cloth diaphragm as it has been found that a hood of metal over the small hole in the cover of the pail so arranged that the milker must direct the streams of milk from the cow s teats horizontally instead of perpendicularly answers practically every purpose In other words the contamination of the milk is caused by the dust which falls into the pail from the cow s sides the milker s hands and clothes and the dust that is always circulating in the air especially of a stable

and economically done immediately confronted our dairy expert. He had heard that brewers pasteurize their beer at the breweries, after it has been bottled, and immediately proceeded to investigate the process to find out, if possible, whether it could be used to advantage in pasteurizing milk. As a result of his study, he has installed one or more pasteurizers, similar to those used by the brewers, in which all the milk from his creamery is pasteurized after it has been bottled and a metal cap has been clamped on the bottle, just as the cap is clamped on the bottle of beer. This cap, with the date of the pasteurization plainly stamped on it, is not to be removed until the milk is used for food, so it cannot be contaminated or sophisticated in any way between the creamery and the consumer's table.

Now I have briefly outlined the fundamental principles on which clean and cooperative dairying can be carried on and milk produced and sold at a profit at 9 or 10 cents a quart.

Of these fundamentals, the most important one, however, has only been hinted at. It is necessary, therefore, to enlarge on it somewhat more fully.

It was said above that the main factor in the production of safe and wholesome milk at a moderate price is the dairyman. I have spoken of the injustice and futility of expecting the farmer to produce a higher-grade milk at an increased cost and not allowing him to participate in the increased profit accruing from its sale. Yet no one appreciated, until the experiment was actually tried, how potent a factor this same farmer is in the production of milk of a satisfactory quality. When our dairy doctor got his creamery started, he refused to accept milk having a bacterial content of over 10,000 per cubic centimeter, and all his farmers brought him milk just below that count, but never much below it. After thinking this over for a while, the bacteriologist in the company's employ spoke to one of the farmers about it and was surprised at the reply that there was no object in bringing cleaner milk, so long as the milk they were bringing would be accepted. Then the creamery adopted another device. It offered $40 a month in prizes, $25 first prize, $10 second prize and $5 third prize, to the farmers bringing the milk that had the smallest bacterial content during the month. A great rivalry at once arose among the milk-producers, and men whose milk had never shown a bacterial content below eight or nine thousand immediately began bringing milk having only a few hundred bacteria per cubic centimeter. The farmer was not told that he must wash his hands carefully between each milking and carefully wash the cow's flanks and udder and sprinkle the stable floor with water before milking, but under the stimulus of the prize and the chance of surpassing his colleagues, he "got busy" and found out all these things for himself and put them into practice, and again the results have been most expectedly satisfactory to all concerned.

These farmers were not ordered to have their cattle tuberculin-tested; they were paid to do it. They were given one-half a cent a quart more for their milk if it was brought from tuberculin-tested cattle. They were also given one-quarter of a cent a quart if their bacterial content was less than 10,000 per cubic centimeter. They were also given 4 cents a can (1/10 of a cent a quart) for every "point" above 3.5 per cent. of butter fat (a point being 0.1 per cent.) and they agreed to pay a penalty of 1/10 of a cent a quart for every "point" below 3.5 per cent. of butter fat in the milk delivered at the creamery.

Now we have a nearly complete cooperative scheme in which the farmers and the creamery are equally interested. The creamery, of course, belongs to the company and all the pails and cans used in holding and transporting the milk are sterilized at the creamery. The farmers get their sterile utensils at the creamery every day and bring them back the next morning filled with milk, leaving them there and taking others away with them for use that night and the next morning.

The bacteriologist is employed by the company and every day he examines every farmer's milk and posts the results on a bulletin board where everyone can see them, so that the farmers all know exactly where they stand and where their competitors stand every day of the month, and who is likely to get the prizes; and if a man fails to keep up his record, he and his neighbors immediately know it and generally can find the reason. The practical benefits of this daily supervision of the milk were strikingly shown not long ago. A farmer one day brought in some milk that showed a greatly increased number of bacteria above his average count. When this was pointed out to him he had no idea of the cause. The bacteriologist, according to his custom, hastened to the farm and inspected the herd. He found three cases of garget, an infectious disease of the cow's udder, which is supposed to convey scarlet fever to human beings who may drink the milk of the affected animal. These three sick cows were immediately isolated and a possible infection of the whole herd was prevented, as well as a possible epidemic of sickness among the consumers of the milk. It is easy to imagine that many human lives might have been saved had this custom of daily bacteriologic examinations of all the milk from every dairy been carried out in the past. It is so useful, so simple, and so practicable, that it does not seem unfair to predict that the dairy laws will eventually enforce this precaution in all creameries and public milk stations.

On another occasion a farmer brought to the dairy some milk showing an extraordinarily large bacterial content. At first he stoutly denied any known cause for this, but, on being cross-questioned, acknowledged that he had bought some milk from a neighbor and turned it in as his own. So an attempted fraud was discovered and frustrated.

Now we see some of the benefits to which cooperation in the dairy business and milk business leads:

1. A comparatively high and safe grade of milk produced at a price within the reach of practically all users of milk.

2. A contented and intelligent body of farmers producing this milk and getting a tangible reward for their improved methods. As they are now beginning to see the advantages of cleanliness they are beginning to practice it assiduously and to believe in it. Instead of looking on health and sanitary regulations as an imposition and a hardship, they are cheerfully carrying them out and are taking pride in their work, and they are also reaping a pecuniary reward, as it is just and proper that they should. This cooperative dairying has opened a new vista before the farmer and has instituted in his business methods and ways of thought an improvement that promises great things for the future. The dairyman has had a hard time for many years, and the result has been the poorest milk that he could get the milk companies to accept, with the consequent large infantile sickness and mortality in all our cities.

The attempt to make him produce high-grade milk by passing ordinances has proved as futile as the long continued attempt, so popular in this country, to make people moral and abstemious by law Education, an appeal to the farmer s self-respect and an assurance that he will be a participant in the increased remuneration for furnishing milk that is safe for a baby to drink, will inevitably work out a revolution in the milk industry

Our dairy doctor is an unquestioned philanthropist and his efforts will tend to raise the whole milk-producing business from its present low and unsatisfactory state into a profitable and respectable — I might almost say, a scientific — calling that may well engage the entire time and thought of any well educated and refined young man or woman

42 Church Street

ABSTRACT OF DISCUSSION

Dr Arthur R Reynolds, Chicago It has been pretty well demonstrated that farms can produce any kind of milk that is wanted, if they are paid for it as they should be

With all the papers, ordinances and things that are read and passed, very little has ever been said about the age of milk It is well known that milk has germicidal properties up to the time that it is about 6 hours old, and also that cows are milked every twelve hours A great many people in the country and smaller places can get their milk every twelve hours, every city should get some of their milk every twelve hours

Dr Malcolm C Rose, New York It was not quite clear what kind of cover or fastener Dr Newton suggested to hold the cheesecloth in place Many farmers would like to know of such a simple device to produce clean milk, rather than go into all the detail required for qualification for the certified class

Dr J Joseph Kindred, Astoria, N Y There is an important relationship between what Dr Newton has said as to the price of milk which the farmer gets and the price which the consumer has to pay And this brings out the point that there is no economic, basic foundation for the fact that the poor consumer and the starving parents of sick babies have to pay the price that they are now compelled to pay In other words, there is no relationship between the law of supply and demand, and even if the farmer is able to sell his milk at a fair profit, the consumer ultimately has to pay an outrageous profit, and we understand, of course, the reason for it, it brings up the very broad proposition of the regulation of the trusts

Dr Joseph Goldberger, Washington, D C I think we all agree that we want primarily a pure milk, and we all will agree that there is a possibility of obtaining it but the difficulty in practical life is to keep it pure during its transit from the cow's udder to the mouth of the consumer Now, while this may theoretically also be possible, as a matter of practical fact it is only too frequently not attainable, and therefore we must try to take such measure or measures as will insure a supply of milk safe in the sense of being free from disease producing organisms

There can be no question but that pasteurization does make milk safe Some of the objections to pasteurization to which Dr Newton referred undoubtedly are valid but as he also well pointed out, when weighed against the points in favor of making the milk safe to the consumer, they must fall out of practical consideration To emphasize, therefore, I simply want to say that we must pasteurize our milk at least in large cities, to increase the chances of the consumer getting a safe, disease free milk Speaking for myself I have not, in my own family, altogether confided in that I am speaking now of commercial pasteurization I do not entirely trust milk even after it has been commercially pasteurized. In my own family I invariably use boiled milk and I am bringing up two vigorous youngsters in that way They have never had any milk (except their mother s for a short period in infancy) that was not boiled, and I do not believe that boiled milk has hurt them in the least

Dr J J Kindred, Astoria, N Y May I ask Dr Goldberger if it is possible to sterilize the whole quantity of milk consumed in the city?

Dr. M. P Ravenel, Madison, Wis I would like to combat the wide spread idea that pasteurization destroys the nutritive value of the milk and produces scurvy and malnutrition in children Pasteurization must always be a temporary measure and should not be advocated to take the place of clean milk from healthy cows It seems to me that one can liken the case to the choice between a pure mountain spring and filtered water from a cesspool, theoretically, the filtered cesspool makes a safe drinking water but people do not want it and it is better to take a water which is pure at its source In the same way it is better to have pure certified milk than pasteurized Nevertheless, pasteurization is a great safeguard and should be adopted where an absolutely clean supply can not be obtained The charge that pasteurized milk produces scurvy has been answered repeatedly I once heard Dr Isaac A Abt, in reply to such an accusation, say that he had seen children with scurvy who fed at the mother's breast, which is unquestionably true I wish to emphasize the value of pasteurization as a measure for the protection of children against diarrheal diseases and tuberculosis and to say further that it does not interfere with the nutritive value of the milk

Dr Richard Cole Newton, Montclair, N J I have always had a prejudice against pasteurization of milk I was brought up in a community where it is the custom to cry down this process saying that it may produce scurvy in children In these days babies are getting a more liberal diet than formerly We tell mothers to give them apple sauce and so on earlier than we used to do Like Dr Ravenel, I have seen very little scurvy or rickets of late, and it is almost criminal for a man to have much of them in his practice, because they are so easy to avoid

One or two of the discussers have asked how the cloth diaphragm is used One farmer, who had a dirty old barn and was very poor, just took a clean rag and tied it with a string over the top of an ordinary open pail He took his milk to a hotel which used a lot of milk, and his milk was found to be the cleanest of any that was brought there The milk pail that was originally used had a cover that fitted on the top like the covor on any kind of a pail There was a circular opening in the cover 3 or 4 inches in diameter, across which the cloth was stretched There was a rim around this opening about 2 inches high and a cap or ring, pushed down over this rim, held the cloth fast The cloth was renewed for every one or two cows It has been found as good or nearly as good to use a metallic hood over this opening, and when the men milk, the stream of milk is directed horizontally into the pail Cloth diaphragms are not used in some of the large dairies nowadays Nearly all the dirt in the milk comes down out of the air as dust and may be arrested on the top of the hood

Dr Reynolds spoke about the length of time between the milking and the delivery of the milk to the consumer Unfortunately, in New York City it does not seem possible to get the cows and the children very near together It was said that years ago an experiment was tried in Paris on foundlings nearly all of whom were syphilitic and practically all of whom died very young female asses were driven up to the foundlings so that the children could suckle them with the result that many of them lived—a striking illustration of the advantage of feeding babies warm milk There is no question about the enormous advantage of this procedure but in New York and Brooklyn it seems impossible so we have to rely on pasteurization Milk can be sold at a profit when sold in the manner described in my paper—at 10 cents a quart, that is about as cheap as clean milk can be produced

JOSEPH HEAD, M D, D D S
PHILADELPHIA

Enamel softening has been considered to be necessarily associated with roughening of the surface, loss of luster and dissolution of the cemental substance that binds the enamel rods together, and whenever enamel decalcification is associated with decay of dentin this conception of enamel softening is only too accurate. But this conception seems to be only a part of the story, so to speak — the final part rather than the complete process of enamel degeneration.

For instance, 1 to 1,000 lactic acid and water at mouth temperature will cut tooth enamel in thirty minutes with a rough white surface. A tooth placed in 1 to 500 lactic acid and some salivas will be unharmed. A tooth placed in this solution made with other salivas, after three or four days may show the enamel perfectly smooth and to all appearances normal, and yet it can readily be pared to a slight distance with a lancet. A 1 to 500 saliva and lactic acid solution has an extremely acid taste and instantly turns litmus brilliantly red. A 1 to 20,000 lactic acid and water solution will, at the end of three or four days, leave the tooth enamel unharmed to all appearances, and yet the outer surface of the enamel will, with the edge of the lancet, be found to have distinctly softened. A 1 to 500 lactic acid solution with my saliva, although the solution has a decidedly acid taste, will produce this identical effect. The appearance of the enamel is unchanged but distinctly softened to the cut of a lancet, although before the tooth has been immersed the lancet is unable to make any impression on it.

The action of water solutions of acid calcium phosphate and acid sodium phosphate on the teeth has been mentioned by Kirk, stress being laid on the fact that these salts cause smooth white decalcification. As a matter of fact, many acids in water solutions cause smooth primary softening, if the solution is sufficiently weak. Saliva ordinarily restrains the action of most acids up to a certain point, and then begins with the smooth decalcification and ends with the same rough white decalcification that we find in a water solution. The saliva solution is ordinarily from ten to twenty times weaker in its action on enamel than is a water solution of the same acid strength. The acid sodium phosphate and acid calcium phosphate are, however, intensely interesting in their action, not only in water solutions but in saliva solutions. Acid calcium phosphate 1 to 5 000 water solution, and acid sodium phosphate 1 to 20,000 water solution at the end of two days, will turn tooth enamel into a cloudy, pearly white, with a clean smooth surface. This surface is distinctly softened to the cut of a lancet. If, however, these teeth are removed from the solutions before the process advances too far the cloudy appearance will in time disappear, and the tooth enamel will resume its normal appearance. This phenomenon occurred many times, but once when I retested the hardness of these teeth with a lancet I found that not only had the white color disappeared but the superficial softening of the enamel had disappeared also. At first I attributed this disappearance of the softening of the enamel to previous faulty observations, but the same phenomenon occurred in my lactic acid test. A tooth that had been placed in a 1 to 20,000 lactic acid watery solution, at the end of a few days was slightly softened to the cut of the lancet, but a month or so later the lancet would not cut it. It was then that the possibility was made apparent that partially softened smooth enamel could reharden itself if the decalcification had not progressed too far.

I then made the following test. Two sound teeth with enamel impervious to the lancet were each placed in a lobe of a navel orange. These lobes were each placed in a bottle with a few drops of ether to prevent fermentation, and kept at body temperature for two days. At the end of that time the teeth were removed and examined. The lobe around one of the teeth had fermented, the lobe around the other had not. The tooth in the fermented lobe showed a smooth, white, translucent area of decalcification, running from the cutting edge to about one-third of the distance to the neck. The rest of the enamel was normal to all appearances, and yet the surface, both of the white and the apparently normal enamel, was readily pared with a lancet. The lobe in which the other tooth was embedded had not fermented, and the enamel also seemed normal, but here again the outer surface of the tooth enamel was distinctly softened. These teeth were then washed in water and kept in some of my saliva at body temperature for two weeks. At the end of five days there was a decided rehardening of the enamel surface, and the white area of decalcification on the tooth mentioned had half disappeared. At the end of ten days the enamel could no longer be scratched with a lancet, at the end of two weeks the white spot of decalcification had almost if not entirely disappeared, and both teeth appeared perfectly normal.

That saliva does possess the power of restraining enamel from carbon dioxid decalcification was proved as follows. A sound extracted tooth was placed in a sparklet or automatic soda water former, where the liquid within could be charged from a carbon dioxid cartridge. Thirty cubic centimeters of saliva were added which had been obtained by chewing rubber. The saliva was then charged with carbon dioxid and the sparklet placed in a culture oven at a temperature of 98 F for thirty days. At the end of that time it was taken out and appeared unharmed. The tooth was then washed with a little ether and replaced in the syphon with distilled water. This water was then charged with carbon dioxid and the flask replaced in the culture oven for twenty-four hours. At the end of that time the enamel showed a chalky decalcification that could be scaled off with the finger nail.

This protective power of saliva is also exerted against lemon, orange, grape, grape fruit, strawberry, rhubarb and cherry, the special action of which was the subject of a paper[1] I wrote in 1908.

These experiments with extracted teeth, weak acid solutions and tests with a sharp lancet in the hand, while suggestive, seemed to me not sufficient to establish so reactionary a doctrine, so while morally convinced of the truth of my assertion that softened enamel could reharden, I immediately started to perfect a machine that would show in the minutest degree just how far a given force would drive a standard punch into sound enamel, partly decalcified enamel and rehardened enamel, if it did reharden, from the effects of slight decalcification. I will not dwell on the discouraging task of making good mechanics work with a scientific

conscience. They would not do as they were told, and much of the adjustment had to be done by the deviser of the instrument, which from at first having an error of 1/500 of an inch, finally developed into a microdynamometer that could deliver 475 pounds pressure on a punch, the penetration of which could be measured up to 1/600,000 of an inch. Something approaching this accuracy was necessary as it was found experimentally that the scope of the average test lay usually within 1/10,000 of an inch. It was, however, decided to set the register so that it would measure in units of 1/300,000 of an inch, which as can readily be seen could be reduced by a table to microns or tenths of microns, one micron being equal to 1/25,000 of an inch, twelve of the machine units, therefore, being equal to one micron. The pressure was given by a mercury gauge to which the punch was attached. A micrometer screw supporting the anvil on which the specimen for testing was to be placed was strongly connected by castings and heavy drawn steel rods beneath the mercury gauge and punch. The pressure was applied to the specimen by placing it on the anvil and raising the anvil by the screw up against the punch until the mercury marked the pressure desired. The penetration of the punch into the specimen was made known by a microscope equipped with a specially constructed filar micrometer, which microscope was solidly screwed to the anvil. This microscope was then adjusted and set so that it could accurately divide into the desired number of parts a glass scale attached to the punch. By this device, all error in the use of the machine was largely thrown out, since only the relation between the punch and the anvil was within the scope of measurement.

In making the various tests three punches are used: a heavy steel punch with a flat hardened circular point 1/50 of an inch in diameter, an iridium pointed punch 1/50 of an inch in diameter for testing acid erosion, it will stand up to 25 lbs. without showing compression; a diamond-pointed punch with a circular, flat point 1/50 of an inch in diameter that can be used in acid solutions and will also readily stand 100 lbs. pressure. Twenty-five pounds pressure with the diamond point will give a penetration equal to 75 lbs. with the steel point. This is no doubt due to the greater sharpness of the diamond edge over the steel.

If, therefore, the specimen is so adjusted and set under pressure that there will be no give between it and the anvil, it is possible to determine accurately within, say, one-tenth of a micron, just how far the punch would penetrate under a given pressure. For instance, the specimen is carefully ground with a Reichert section grinder so that there is a flat, large base. A small spot on the top of the enamel is ground parallel to the base. This forms the area to be tested. Any pressure exerted on the enamel spot by the punch is directly expended on the enamel, without any side give between the base of the specimen and the anvil. The specimen with parallel sides is placed on an agate slab and the slab placed on the anvil. The punch is adjusted near the edge *of the ground enamel and given a pressure of 5 pounds*. A reading by the microscope attached to the anvil is then taken on the scale attached to the punch. The pressure is then raised to the desired amount, say, 75 pounds, for a given time, and then the pressure is reduced again to 5 pounds and another reading taken, the difference on the scale representing the penetration of the punch. To shift the specimen under the point for the different measurements the agate slab is moved, not the specimen on the slab. This eliminates variations in the spring of the specimen, since the compression of the parallel slab on the anvil under a given pressure, will always be the same.

Five or more measurements are usually made for each reading and the average taken. By this means the density and strength of normal enamel can be shown as can also the variations from the normal enamel caused by strong acids, water solutions of acids, saliva, fresh and stale acid saliva solutions, and the recovery of enamel from the effects of a slight acid decalcification and the rehardening of its surfaces after it has been ground with a stone.

All analytical analyses of saliva heretofore have been hampered by the fact that the investigator of it first started by chemically breaking it up, thus largely destroying it as saliva. All analytical investigation of saliva from a dental point of view up to the present time, has been of little value owing to the fact that normal saliva may be alkaline to lacmoid or congo red, neutral to litmus, and acid to turmeric paper, all at the same time. How saliva reacts to lacmoid, litmus or turmeric may be purely of academic interest, but how it may react on enamel and dentin is a vital question that interests every man that lives, and this machine has, it is hoped, made it possible for enamel to be its own indicator of how a saliva may affect it. Since the first days of physiologic study, saliva has been a most tempting field for investigation because it is the body secretion most easily obtained in a living state. It ought to be at least of equal value to the diagnostician as urine, but up to the present time it has not been. This may lie in the fact that saliva is a living substance and urine is an effete product that lends itself to a chemical analysis that would absolutely destroy saliva as saliva. Chemical analysis that breaks up the individuality of living saliva is of little more value in showing the vital action of saliva than fried chicken would be in showing the beauties of a cock fight.

I am far from discouraging saliva analysis of any kind. Epinephrin may illustrate the living secretion of the suprarenal capsule or it may not. Salivary extracts or chemical products are interesting but inconclusively related to the living action of the secretion and, therefore, while enzymes of a curious and even therapeutic nature may be extracted from saliva, no one can prove that they justly represent the action of the living secretion unless some means are devised to make control tests with the living saliva that show the corresponding action. This machine, it is hoped, will make it possible to test on tooth enamel the acid restraining power of various living salivas in relation to a standard water solution of acid. Salivas vary in this power. The same saliva may vary at different times, apparently according to the condition of the patient.

The conditions then are as follows: During sickness the teeth, from clinical experience, are known to decay. This may be due partly to acid medicine or lack of care, but with every allowance for these sources of error, it seems to be well established that severe or chronic illness *in some way may render the teeth sensitive to deterioration*. Formerly it was supposed that some product was extracted from the enamel through the blood circulation but this is now fully disproved by the histologic knowledge that human tooth enamel is, to all intents and purposes absolutely shut off from the blood current. If a relation between ap [illegible] loss of acid protecting power [illegible] lished, a beginning in the saliva would have been example, the test that was made on a specimen of tooth enamel that I use for an illustration One side was ground to a flat, broad base, on the other side the enamel was ground in a small corresponding parallel plane This was placed on the anvil of the machine and raised up against an iridium point 1/50 of an inch in diameter until a pressure of 5 pounds was reached A reading was then taken on the micrometer scale and noted The anvil was raised up and down repeatedly until all give between the specimen and anvil disappeared, and the 5 pounds pressure always gave the same reading Then fresh lemon juice and water 1 to 100 was placed on the specimen around the point and the point relaxed so that the fluid could readily get underneath At certain intervals of time the pressure of 5 pounds was tried and a reading taken which showed a loss of tooth structure as follows

2	minutes	0 8	micron
5		1 2	
10		1 4	'
35	'	2 3	
60	'	2 8	"

Thus, in one hour there was a loss of 2 8 microns of tooth enamel This same test was then made on the same tooth enamel with a fresh saliva solution of lemon juice, 1 to 100 This solution turned litmus red and was distinctly sour, and yet after an hour's application the enamel showed a loss of only 0 3 of a micron We might, therefore, express the restraining factor of that saliva as 28 3 or 9 Numerous other tests have been made of a similar nature and all seem to give consistent figures They almost invariably seem to prove the power of saliva to restrain the action of lemon juice on enamel They also show that some enamels are much more resistant to decalcifying action than others

As an illustration, another test might prove interesting This specimen was ground longitudinally for a base along its axis and a small parallel plane ground on the enamel of the opposite side *A solution of 1 to 100* lemon juice and water applied for an hour dissolved 1 0 micron Saliva and lemon juice, 1 to 100, applied for sixteen hours showed no loss of tooth tissue at all It was then tested with the steel punch 1/50 of an inch for density and was found so softened that from 60 pounds to 70 pounds pressure could not be obtained The softened enamel simply refused to support the punch under such a pressure The specimen was then placed in fresh saliva and set in the culture oven at blood heat for seven hours, the saliva being changed every half hour At the end of that time the tooth was again tested with the steel punch and was found to have so hardened that 75 pounds pressure was readily withstood and a various penetration noted of 3 5, 2 8, 3 2, 4 5 microns No doubt it would have hardened up more but the various testings had so strained the specimen that it was considered advisable to continue with others The great softening and hardening apparent in this last test is no doubt due to the enamel being very thin so that the variations were partly due to the dentin underneath But tests on two bicuspids extracted from the same mouth for the purpose of regulation, with perfect enamel, to all appearances show conclusively that enamel has an extraordinary power of hardening and softening under various conditions, although no acid solvent at all was used

These specimens were soaked for about ten days in a 1-to-10 dilution of liquor formaldehydi in water They were then cut flat at the neck and 1/80 of an inch ground off the cusps of Specimen 1, and 1/50 of an inch ground off the cusps of Specimen 2 The diamond point was used at 25 pounds pressure

Specimen 1 (buccal cusp) when freshly ground gave an average softness of 1 5 microns, the readings being 1 1, 2 0, 1 2, 1 3, 1 8, 1 2

Specimen 2 (buccal cusp) gave an average softness of 1 6 microns, the readings being 1 2, 1 6, 1 6, 1 5, 2 1

Specimen 1 (lingual cusp) gave an average penetration of 1 2 microns, the readings being 1 3, 1 2, 1 3, 1 2, 1 0

Specimen 2 (lingual cusp) gave an average penetration of 1 1, the readings being 1 3, 0 9, 1 1, 1 3, 0 9

Here in two specimens, apparently of similar teeth from the same mouth, we find the buccal cusps having *the same hardness with 0 1 of a micron, and the same* with the lingual cusps, while the lingual and buccal cusps on the same teeth show a variation in penetration of from 0 5 to 0 3 micron respectively

I speak of this comparison to show the consistency of the machine measurements I shall now proceed with the tests on Specimen 1

After being tested the specimen was placed in distilled water for three hours and again tested The buccal cusp had softened from 0 3 micron to 1 8 microns, the measurements being 1 4, 2 4, 3 9, 1 9 The lingual cusp had not changed, showing a penetration of 1 2 microns, measurements being 1 5, 1 3, 1 3, 1 3, 0 8

The tooth was then placed in J H saliva over night.

In the morning the buccal cusp showed a slight hardening of one point, to the average hardness of 1 7, the measurements being 1 8, 1 3, 1 8, 2 2, 1 6

The lingual cusp had hardened 0 2 to the average of 1 0, measurements being 1 1, 1 2, 1 0, 0 8, 1 1

The tooth was allowed to stay in J H saliva, at room temperature, all day (nine hours) and tested again, when the buccal cusp had hardened seven points, to the average of 1 0, measurements being 0 9, 0 8, 1 2, 1 0, 0 9, while the lingual cusp had hardened 0 1 to the average density of 0 9, measurements being 0 4, 0 7, 1 1, 1 3, 1 1, 0 7 In this instance, the buccal cusp started at 1 5, softened to 1 8, and hardened to 1 0 The lingual cusp started at 1 2 and stayed the same, or consistently hardened to 0 9

It was decided to try the saliva of my assistant on this specimen

The specimen was placed in incubator, 98 F, with A J F saliva and a little ether for 36 hours, and buccal cusp showed a softening of 0 5 or an average of 1 5, measurements being 1 7, 1 4, 1 2, 1 4, 1 5, 1 5 Lingual cusp remained the same or 0 9, measurements being 1 0, 0 8, 0 8, 1 2, 0 6 The specimen was kept in A J F saliva for a day longer, when the buccal cusp showed a further softening of 0 7, penetration being, 2 2, the measurements being 1 4, 3 4, 1 5, 2.0, 2 6 The lingual cusp showed a softening of 0 3, having an average penetration of 1 3, measurements being 1 6, 1 6, 1 4, 1 1, 1 0

The specimen was then placed in a 2 per cent dilution of liquor formaldehydi in water for sixteen hours, room temperature, when the buccal cusp was found to have hardened 1 2 to 1 0, measurements being 1 3, 0 8, 1 0, 1 0, 0 8, and the lingual cusp had hardened from 0 1 to 1 2, measurements being 1 4, 0 8, 1 0, 1 8, 0 9

Specimen 2 The buccal cusp showed a hardness of 1 6, the lingual cusp a hardness of 1 3 It was placed in A J F saliva and 2 per cent ether in incubator at 90 F for three and one quarter hours and tested again The buccal cusp had hardened 0 5 points to 1 1, measurements being 0 9, 1 0, 1 2, 1 2, 1.2 The lingual cusp showed a hardening of 0.2 points, having an average of *0 9*, measurements being 0 8, *1 0, 1 3, 0.9, 0.8, 0 9* The specimen was then replaced in the same saliva in the incubator for two days and the buccal cusp showed a further hardening of 0 1 point, giving a penetration of 1 0, measurements being 0 5, 0 8, 1.2, 1 2 1 0 1 2, 0 8

The tooth was then placed in J H saliva, at room temperature for eight hours, when the lingual cusp showed a softening of 0 6 point or an average of 1 5, measurements being 1 2, 1 4, 1 1, 1 9, 1 9, 1 7, 1 0

The tooth was then placed in A. J F saliva, in incubator for fifteen hours, when the buccal cusp was found to have softened 3 points to 1 3, measurements being 1 4, 1 3, 1.3, 1 2, 1 2, while the lingual cusp had hardened 5 points to 1 0, measurements being 0 9, 0 9, 1 0, 1 1, 1 1

The specimen was put in A J F saliva in incubator and the saliva was changed every half hour In four hours, the buccal cusp had hardened 2 points to 1 1, measurements being 1 2, 1 2, 1 1, 1 2, 1 0, 1 2, 1 0, while the lingual cusp remained about the same, showing also a penetration of 1 1

The specimen was then placed in A. J F saliva and 2 per cent ether in incubator for twenty four hours, when the buccal cusp was found to have softened from 0 5 points to 1 6, measurements being 0 9, 0 8, 2 1, 1 4, 2 8, 1 6, 1 4, and the buccal cusp had softened 0 2 point to 1 3, measurements being 1 4, 1 3, 1 2 1 2, 1 3

Then 5/1000 of an inch was ground off the tooth surface and the cusps were again measured to see how they would compare with the original tests The buccal cusp showed an average penetration of 1 7, one more than the original test, measurements being 1 7, 1 8, 1 6, 1 8, 1 6, while the lingual cusp showed exactly the same hardness, having a penetration of 1 1 The tooth was then placed in the incubator with A J F saliva changed every half hour for six hours The buccal cusp hardened 0 4 point to 1 3, measurements being 1 9, 0 9, 1 2, 1 3, 1 0, 1 6, 1 2 The lingual cusp had softened 0 1 point to 1 2, which was practically remaining the same, measurements being 1 2, 1 4, 1 2, 0 8, 1 2, 1 4

The tooth was then placed in A J F saliva and ether in incubator over night, when the buccal and lingual cusps showed an equal penetration of 1 3, the buccal measurements being 1 4, 1 0, 1 6, 1 4, 1 3, and the lingual measurements being 1.2, 1.2, 1 4, 1 2, 1 4

This softening and hardening of enamel has a very practical bearing in relation to mouth cleansing and the use of brush and dentifrices Enamel that in its hardest state would only show insignificant wear to dentifrice grit and friction in a temporarily softened state may, through a good brushing with grit, lose a very material amount of tooth structure This softening and hardening may readily account for the reason why some patients, especially those fond of fruit, wear their teeth down to the gum, at a comparatively early age The mere friction of mastication is sufficient to take off a layer of enamel softened by fruit or vinegar, which if left to itself might reharden

I have made hundreds of tests with this machine, but as these are largely of interest to dentists I will reserve them for another paper, where there will be ample space for the tables that should, of necessity, accompany my findings concerning the variations in the action of enamel, which variations are so extraordinary as to be almost beyond belief

But that enamel will harden and soften within certain limits, I am convinced And that this hardening and softening is influenced by the saliva and foodstuffs is to me beyond the question of a reasonable doubt This action I also believe may occur in dentin, but my tests concerning this latter are not sufficiently numerous to serve as a basis for a positive assertion

For those who are interested I give a more detailed description of the microdynamometer for measuring the hardness and softness of tooth enamel This machine can measure to 1/600 000 of an inch just how far a standard punch will be driven into enamel by a standard force

It is now gauged to measure to 1/300,000 of an inch, which being 1/12 of a micron, the figures are mathematically reduced by a table to 250/1000 of an inch, or tenths of microns, so that as microns or tenths of microns, they can be easily understood at a glance The tenth of a micron is the unit of measurement used in the table

The pressure is given by a mercury gauge (9) to which the standard punch (2) with glass scale (3) is attached

The pressure is applied to the specimen (1) by placing it on an agate slab with parallel sides (4) and the slab on the anvil (5) and raising the anvil by the micrometer screw and ratchet wheel (8) up against the punch until the mercury gauge makes the pressure desired

The penetration in the specimen is made known by a microscope (6) which is equipped by a specially constructed filar micrometer (7) which microscope was solidly screwed to the anvil (5) This is then adjusted and set so that it can accurately divide into the desired number of parts the 1/1000 of an inch divisions on the glass scale attached to the punch

A counter weight (10) makes the mercury gauge start at 25 pounds pressure as the mercury gauge is not accurate before that pressure is obtained

(11) Electric lights for lighting the specimen and illuminating the microscope

(12) Ratchet screw for raising or lowering the glass scale attached to the punch

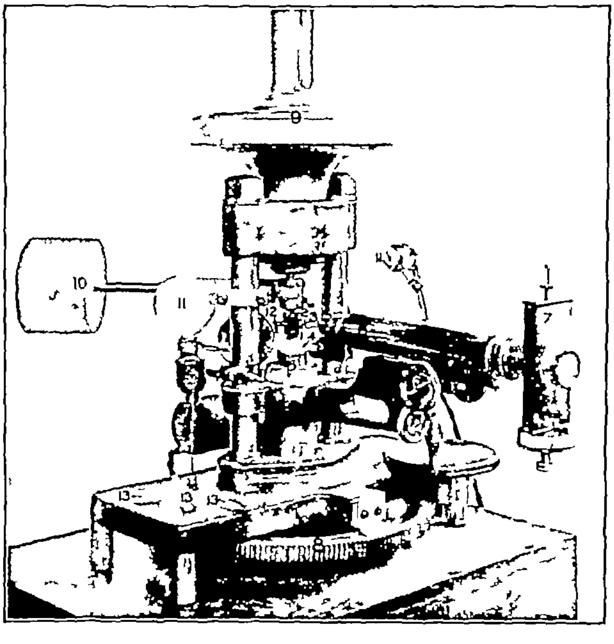

Fig 1 —Full view of microdynamometer with the exception of the top of mercury gauge

(13) Various tooth specimens ground and prepared for action

If, therefore, the specimen is so adjusted and set under pressure so that there is no give between it, the slab and the anvil, it is possible to determine accurately within, say, 1/12 of a micron just how far the punch can penetrate under a given pressure

For instance, the specimen is carefully ground on the microscope grinder until it has a flat, large base and a small spot on the top of the enamel ground parallel to the base It is essential that the spot tested should be absolutely parallel to the base in order to avoid side give

Three punches are used A hardened steel punch 1/50 inch in diameter, designated as A This is used purely for ascertaining how far a penetrating force under varied conditions will drive it into the enamel

A punch consisting of an iridium point set into a brass rod which is used to determine t [illegible] on enamel, whether erosion or swelling

A diamond punch design [illegible] inch i diameter, and used at a [illegible]

All of these punches a [illegible] the anvil at a pressure [illegible] used on the test, as a preliminary to any measurements being taken

The A punch, unless otherwise stated, will be first set at 75 pounds, then the pressure reduced to nothing Then, without moving the specimen in the agate slab that is ground parallel, the slab is moved so as to place a new area of enamel under the point The punch is then placed at 5 pounds pressure and a reading taken through the microscope on the glass scale attached to the punch The pressure of 75 pounds is then exerted for ten seconds, when the pressure is reduced to 5 pounds and a reading taken The difference is the penetration

For various readings on the same enamel surface during a single test, the agate slab is moved as desired, but the specimen is not moved on the slab as that would necessitate a new setting

The same procedure is used with the D punch as the A or B punch The times and pressure varying according to the test desired

The same procedure is followed with B punch where acid action on enamel is to be determined The specimen is set at 10 pounds, then reduced to 5 pounds and released, and again placed at 5 pounds until the same reading is always obtained Then the acid is applied and at desired intervals, the point is placed on the enamel and the readings taken, showing erosion or swelling or a negative result as may be the case

A negative result with the B punch may be followed with tests with the A or D punch that show softening to an astonishing degree

ABSTRACT OF DISCUSSION

Dr G V I Brown, Milwaukee Wis I believe that when Dr Head has established the facts pertaining to saliva and enamel as he has presented them to day and there seems little reason to doubt that they will be established, and when this knowledge may be fitted into its proper niche in the greater structure that is building in the pathology of the different bodily divisions, then saliva will have a significance that we have never before accorded it

Dr C J Grieves, Baltimore I did some work for the American Society of Orthodontists on decalcification of enamel, and I soon found that I knew nothing about the saliva and could not find many who did know anything about it There are many things said, but there is little known as to the difference between living and dead saliva, if I may use that term I found that enamel reacted very differently to these two kinds of saliva Dr Head had done some work along this line in regard to the ordinary aqueous solution and an acid solution in the saliva The mucoid element in saliva is commonly condemned, and rightly so in the carious mouth in which the glycogen or carbohydrate portion is over 25 per cent, for it then becomes the normal habitat of that caries producing organism the decalcifying organism, I believe that normal mucus in the normal mouth is what makes for tooth protection, as it has already been shown to do in the gastro intestinal tract That is what makes the difference between the saliva solution and the aqueous solution

I further found that all alloys were disassociated electrolytically in the mouth and we might well reason that enamel is decalcified by the same process which shortly destroys smooth surfaces of alloys in the mouth, the only substances not subject to disassociation are the mucoid or gelatinous substances, the common mouth mucus belongs to this group and I believe out of the mouth it protected the enamel from acid disassociation in Dr Head's test cases, as I am sure it does by a film in the mouth We all have seen acid decalcifications produced by orthodontia appliances These decalcifications are said to be rubbed out by prophylaxis, but I do not believe this I think that the intercement substance has been destroyed by acid between the enamel rods and the interstices left are filled with mucus and the decalcified spot apparently disappears If it is desiccated, it will then show up as an opaque spot I firmly believe in the protective action of vital mucus in normal cases but not when there is over 25 per cent carbohydrate and the mucus is acid from fermentation In erosion the mucus is nearly all in solution and there are few films on the teeth Every normal tooth is covered by an alkaline film, where there are few films and the mucus is in solution, the action of acid sodium phosphates and calcium phosphates produces erosion

Dr. Joseph Head, Philadelphia I have done this hundreds of times with the same characteristic results I have convinced myself, and now I want somebody else to try it

Dr E S Talbot, Chicago Dr Latham and I have been working on this for perhaps ten or twelve years from the internal point of view We took the ground that these changes in the enamel were due to changes in the blood, and we actually demonstrated pathologic conditions of the dental pulp and the tissues which as far as we went are no doubt correct, but that work does not interfere at all with this work that Dr Head is doing I am not sure but we shall find that the work which Dr Head is doing here will to a great extent solve the problem of decay of the teeth That softening of the enamel and dentin take place through diseases of the body, there is no question We have all seen enamel soften and the teeth decay very rapidly in tuberculosis and other diseases, the point was to prove that softening and decay did take place—I believe that they do—by establishing a degeneration of the dental pulp and the tissues of the cementum and enamel The work which Dr Latham and I have been doing in demonstrating that the softening of these tissues may take place from systemic conditions, added to Dr Head's work, will help to solve this problem It seems strange that this softening and hardening should take place in so short a time

Dr Joseph Head, Philadelphia I cannot explain how these things occur, because I do not know I am simply in a maze of astonishment I am convinced that enamel will harden and soften Since this has come to my attention, I have noticed spots that apparently seem to disappear, and I have had other dentists make the same observations

If that spot disappears, would not this prove that the enamel is not the dead, inert substance that we are supposed to consider it? I cannot help feeling that the enamel is undergoing a series of changes, a sort of unseen action in itself, and that it is capable in its own molecular being of softening and hardening, something similar to the Bermuda rock which hardens under certain conditions It is nothing unusual for crystals to harden and soften again

---

A CLINICOPATHOLOGIC STUDY OF CARBON MONOXID POISONING*

J W McCONNELL, M.D
AND
WILLIAM G SPILLER, M D
PHILADELPHIA

REMARKS BY DR MC CONNELL

Through the courtesy of Dr Charles K Mills I am enabled to make this report of a fatal case of poisoning by carbon monoxid, the patient having died in his service at the Philadelphia General Hospital As a recital of mere symptoms is almost valueless in these days of search for ultimate conditions, Dr William G Spiller kindly undertook the pathologic study and by his unusual findings established a sufficient reason for this presentation I take this opportunity of expressing my appreciation of Dr Spiller's kindness in associating his microscopic work with my clinical study

---

* Because of lack of space this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the authors reprints

* Read in the Section on Nervous and Mental Diseases of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912

* From the Department of Neurology and the Laboratory of Neuropathology of the University of Pennsylvania and from the Philadelphia General Hospital

Poisoning by carbon monoxid may be divided into three great classes, the division being determined by the mode of onset of the symptoms acute poisoning, chronic poisoning and relapsing carbon monoxid poisoning

Under acute poisoning are included those cases in which the manifestations appear very promptly after the exposure of the individual to the toxic agent, whether such exposure be accidental or intentional The symptoms include nausea, an indefinite feeling of illness with fulness of the head, headache, vertigo, great muscular weakness, and, if the influence of the gas is continued, drowsiness, unconsciousness and loss of control of the sphincters Muscular twitchings or even convulsions sometimes occur The skin and mucous membranes may be cyanotic and occasionally an erythematous rash resembling frost-bites may be seen over the malar prominences

The sequelae of acute poisoning include pneumonia, cardiac palpitation, localized hyperemias, gastro-intestinal disturbances, transient glycosuria, cutaneous eruptions, localized edema and gangrene In the nervous system, paralyses of central or peripheral type and choreiform movements are seen, persistent headache is complained of and mental changes take place, often only mild hallucinatory states but more commonly distinct confusional insanities

Under the heading of chronic poisoning by carbon monoxid are placed those cases presenting headache, nausea, vertigo, general weakness and anemia with some slowness of intellectual activity and failure of memory These are all symptoms of the acute type, but appear gradually in individuals who are chronically exposed to the toxic action of carbon monoxid

The third class is designated as relapsing carbon monoxid poisoning, a term used to indicate the condition in those who, having apparently recovered from the initial effect of the poison, develop after a period of fair health a grave type of symptoms leading to death Coplin, in 1905, explained the condition most uniquely, but without basis of fact He said

> In gas poisoning there takes place a combination of carbon monoxid with the hemoglobin of the hematoblasts present in the bone marrow The blood making process is so crippled that when old injured cells are worn out and must be replaced there are no new cells prepared

The occurrence of relapsing carbon monoxid poisoning was explained by Becker and Schwerin on the basis of a "deep-seated disturbance of the regeneration of all organs, especially of the vascular walls and the ganglion cells of the nervous system, as is evidenced by the secondary hemorrhages, idiocy, imbecility, etc, which are observed as sequelae"

Accounts of individuals suffering from relapsing carbon monoxid poisoning are not rare, and I could consume time and patience in reciting cases illustrative of the type of disease under discussion One or two, however, that are strikingly similar will suffice for the purpose

A man, aged 69, a porter, whose case was reported by Simon in 1868, was asphyxiated by carbon monoxid His recovery was marked by persistent vertigo and headache A month after his apparent return to health he developed a right hemiplegia quickly followed by death Simon also reports the case of a woman, aged 46, who partially recovered from the acute effects of poisoning by carbon monoxid and subsequently developed mental disturbance, convulsions and rigid limbs She was aphasic and died without any improvement in the nervous symptoms Edsall calls attention to the fact that symptoms of much gravity often may be caused by a mild attack of poisoning, but these symptoms cannot be attributed to the immediate effects of the carbon monoxid, for Gruber, Sedgwick and Nichols and many others have fully demonstrated the non-persistence of the gas in the blood

The following is the clinical report of a case which I observed for about six days

Case 1 —*History* —The patient, C S, was admitted to the alcoholic ward of the Philadelphia General Hospital in a stuporous condition, Nov 28, 1911, supposedly suffering from alcoholism There was no evidence of paralysis or other physical disability As the patient did not improve she was transferred to the medical ward on December 1

Except for very slight mental improvement the condition of the patient remained unchanged and she was transferred to the neurologic wards on Dec 13, 1911

From her son it was learned that the patient had always been well, she had never had a sick day until two weeks before admission when she became mopey, dragged her feet, seemed tired and wanted to lie down She talked, took nourishment, did not have pain and made no complaints Her last two days at home were notable because of the loss of control over the bladder and bowels About three weeks before admission she was overcome by coal gas while sleeping She was found unconscious and taken to a hospital where after ten hours she recovered consciousness, and in two days was discharged fully recovered and able to attend to her usual duties This condition of good health lasted but a few days Her family, past medical and social histories are immaterial Her son said that she complained of the stiffness of the upper extremities but attributed it to the artificial respiration movements employed at the hospital

Examination —Dec 14 1911, the patient was examined by Dr Mills and myself She was unconscious, lying on her left side, irresponsive to sensory stimuli, that is she showed no change of countenance when pricked with a pin although the plantar reflexes were very active Her face had the appearance of general muscular contraction giving to it a frowning or stern expression a sort of squeezed expression The corrugatores supercilii the orbiculares palpebrarum and zygomatici muscles were apparently spastic. The jaw was tightly closed

The malar orbiculopalpebral and the fronto orbiculopalpebral (McCarthy's) reflexes were very prompt The left pupil was slightly larger than the right, which was irregular Both reacted promptly to light

The upper extremities were very spastic in the right angle position at the elbows with the arms held close to the sides and the wrists and fingers semiflexed All the deep reflexes, muscle and tendon jerks were plus Those examined were the von Bechterew the coracobrachial the biceps, the triceps and the radiocarpal

The abdominal reflexes were present The patient was incontinent of urine and feces

The right lower extremity was spastic in flexion at the knee and on the pelvis The left lower extremity was spastic less so than the right and almost in extension The deep reflexes were present and somewhat exaggerated probably markedly so but restrained by spasticity Delayed ankle clonus persistent and marked, continuing for some time, was present on both sides

The plantar metatarsal and metatarsophalangeal reflexes were marked The small toes went down but on careful selective minimal stimulation of the soles of the feet the great toes were extended more than their quiet position which was one of permanent Babinski

Course —The condition of the patient steadily became worse with the development of spasticity of the muscles [illegible] tication so that the stomach tube [illegible] were [illegible] nasal feedings which latter [illegible] regurgitation of the liquid [illegible] nd the larynx.

The patient died on Dec. 17, 1911, nineteen days after admission to the hospital and forty days after the asphyxiation by carbon monoxid. During her residence in the hospital she had no fever except the terminal rise of temperature to 103 F. The pulse rate was uniformly fast, averaging from 90 to 100 beats per minute. Respirations were between 20 and 25 per minute, until the final shallow breathing set in. The blood pressure unfortunately was not measured, but at all times to the finger the pulse was soft and easily compressed.

Laboratory studies of the urine showed no albumin, no sugar and no abnormal microscopic findings. Examination of the blood gave 92 per cent. of hemoglobin, 5,890,000 red cells and 14,300 white cells. The Hoppe-Seyler test for carbon monoxid hemoglobin was negative, the resulting color being brown. This was not made, however, until six weeks after the intoxication.

The especial clinical interest in this case lies in the time which elapsed between the initial poisoning and the development of the grave symptoms, in the bilaterality of the motor symptoms, in the intense spasticity present and in the absence of distinct vasomotor or trophic symptoms.

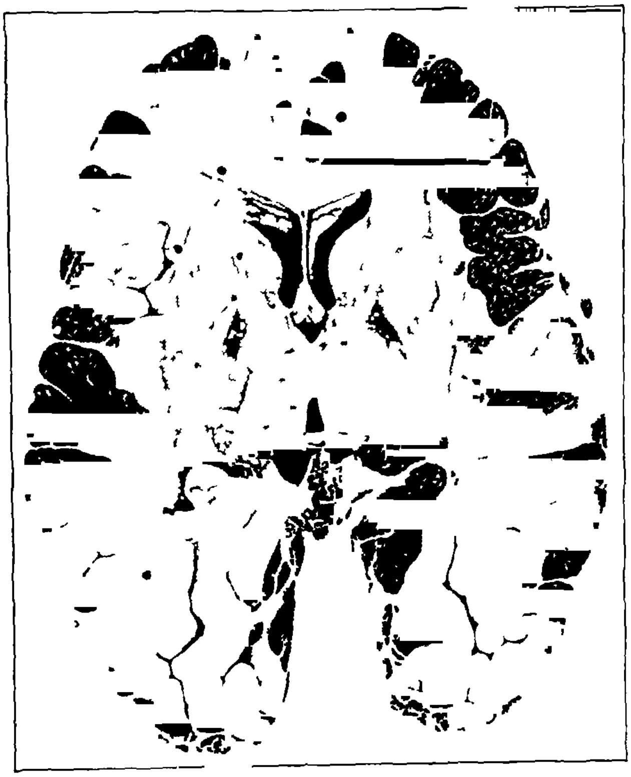

Fig. 1.—Symmetrical areas of softening in the inner segments of the lenticular nuclei.

As I have already stated, the weight of opinion seems to be in favor of the non-persistence of carbon monoxid in the blood and also the non-cumulative action of the gas. There must be, therefore, to explain the relapse, some physical or chemical process, originated by the poison and continuous in its action after recovery from the immediate effects of the acute intoxication. This I leave for Dr. Spiller to elaborate. In the paper by Dana on the functions of the corpora striata the statement is made that "in severe gas-poisoning there is a double softening of the lenticular nucleus due to thrombosis." This is the gross pathologic condition found in many of the reported cases, and fully explains the bilateral motor symptoms which conform to the type spoken of by Mills and Spiller in that the paralysis is less severe in lenticular disease than in capsular lesions.

Finally, many writers call attention to the distinct trophic cutaneous symptoms, but the only suggestion of a skin lesion in this case was the slight erythematous eruption over the cheeks and nose, somewhat like the appearance described by Peterson and Haines. Despite the fact that the comatose state lasted for days there was not a sign of decubitus or any gangrenous process.

REMARKS BY DR. SPILLER

The Betz cells in the case, reported from the clinical aspect by Dr. McConnell, are in a fair state of preservation, and there is little change in the paracentral lobules. The cells of the anterior horns of the spinal cord are well preserved, both in the cervical and lumbar regions. The vessels of the spinal pia and of the pia over the paracentral lobules and medulla oblongata are moderately thickened, and there is a very slight round cell infiltration of the pia.

The inner segment of each lenticular nucleus shows a well defined area of softening (Fig. 1). These areas are almost exactly equal in size, and have almost exactly the same upper and lower limits. The vessels within these areas of softening show calcification of their walls (Fig. 2), so that they stain purple with hemalum, and black by the Weigert medullary sheath method. Numerous round or irregularly shaped masses, most of them having the structure of corpuscula arenacea, are found throughout the softened areas (Fig. 3).

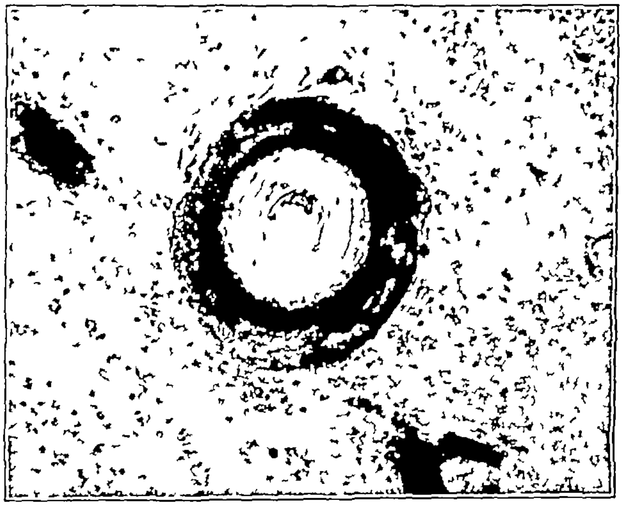

Fig. 2.—Calcified vessel in the area of softening in the lenticular nucleus.

The first thorough study of the encephalomalacia following carbon monoxid poisoning seems to have been made by Klebs; this honor is given to him by Hedrén.[1] Bilateral softening of the lenticular nucleus has been observed for many years as a result of carbon monoxid poisoning, and seems to be confined to the inner segments, but Oppenheim has written in the latest edition of his text-book that the method by which this softening is produced is not fully understood. The symmetrical softening of the lenticular nucleus always suggests carbon monoxid intoxication but it may occur from other causes, as Runeberg has shown (Hedren). In this paper I report a case in which a history of gas-poisoning could not be obtained. The bilateral lesions were not quite so symmetrical as in the case in which a history of gas-poisoning was given.

---

[1] Hedrén: Nord. med. Ark., 1902, ii, 4.

Poelchen,[2] in 1888, was able to collect the reports of twelve cases of bilateral softening of the lenticular nucleus following carbon monoxid poisoning, at least, the inference is that the lesions were bilateral in all twelve cases He also found similar changes in the inner segments of the lenticular nucleus and its vessels in a person dead from phosphorus-poisoning, so that phosphorus seems to have the same effect as carbon monoxid The bilateral softening from carbon monoxid poisoning may be remarkably symmetrical, not only as regards the limitation to the inner segments of the lenticular nuclei, but also as regards extent of the lesions upward and downward Poelchen's explanation of this is that the vessels of the inner segments of the lenticular nucleus are very narrow, even at their origin from the basal vessels, are without anastomosis, without vasa vasorum, and therefore dependent alone on the blood circulating within them The arteries of the outer segment of the lenticular nucleus are comparatively large, and probably anastomose with the arteries of the island of Reil If the carbon monoxid poisoning lasted long enough, other vessels would become affected

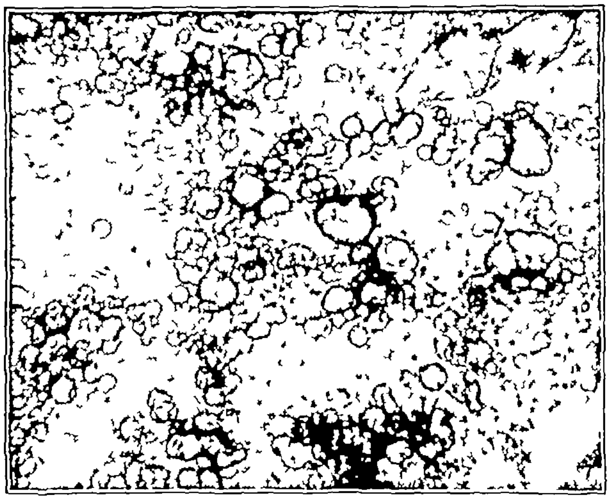

Fig 3—Calcareous deposits (corpuscula arenacea) in the areas of softening of the lenticular nuclei

The most satisfactory explanation for the symmetrical softening has been given by Kolisko,[3] to whom we owe largely our knowledge of the circulation of this part of the brain He states that in addition to the long arteries (arteries of cerebral softening supplying the head of the caudate nucleus, anterior limb of the internal capsule and anterior part of the external segment of the internal capsule) arising from the anterior cerebral artery a number of shorter arteries have their source in this artery which also convey the blood in a different direction from that in the parent stem They are very small, about the thickness of a hair Similar arteries arise from the carotid, the first part of the middle cerebral artery and the posterior communicating artery These fine arteries do not anastomose They supply the anterior part of both inner segments of the lenticular nucleus and the adjoining part of the internal capsule, including the knee The extraordinary delicacy of these vessels with their almost perpendicular course at their origin is the cause of softening in carbon monoxid poisoning In no other part of the brain is the circulation through such short and narrow arteries Kolisko has repeatedly had opportunity in necropsies on those who died a few days after carbon monoxid poisoning to find symmetrical softening in the distribution of these arteries He thinks the great distention of these vessels, which occurs in the early stage of carbon monoxid poisoning and has been known since the time of Klebs, causes thrombosis and a disturbance of the circulation in these vessels

Peterson and Haines[4] state that a large number of experiments on animals forced to breathe carbon monoxid, diluted with either oxygen or air, have resulted in showing that the blood-pressure is at first considerably increased as the result of the stimulation of the vasomotor center A benumbing of this center is then shown by the decrease of the pressure and a distention of the blood-vessels

From this it appears that Kolisko's arteries of cerebral thrombosis are not concerned in the softening of carbon monoxid poisoning, but as some of these fine vessels of which Kolisko speaks have the same course, the change in the direction of the blood-current affects them equally Hemorrhage in the distribution of the arteries of cerebral thrombosis is exceedingly rare Thrombosis, however, has rarely been found in cases of carbon monoxid poisoning Poelchen, Sibelius[5] and other investigators have searched for it in vain, but it was found by Kolisko and by Hedrén

Most extraordinary is the apparently complete or nearly complete recovery from the acute poisoning with recurrence of symptoms, possibly terminating fatally The late symptoms may develop several weeks after apparent health This recurrence of symptoms was observed in the case reported by Dr McConnell, and similar examples may be found in the literature I refer merely to one, as in the extreme spasticity it resembles the case we have studied

Hedrén reports the case of a patient who, having been overcome by carbon monoxid poisoning, was brought into the hospital unconscious and after twelve days was dismissed apparently entirely recovered He continued well three days and then began to have severe headache and pain in the extremities Memory began to fail, general muscular rigidity and stupor developed, and death occurred about twenty-five days after the first return of symptoms The rigidity was so great that the patient was brought from a lying to a sitting position with great difficulty, as he was "stiff as a board" Alteration of the vessels was found in the left lenticular nucleus with thrombosis of the small vessels of this part Small areas of softening and small hemorrhages were found in the spinal cord

How are we to explain these delayed symptoms? There seems to be no support for the view that the occurrence of symptoms immediately or shortly after carbon monoxid poisoning depends on whether illuminating gas or coal-gas was the source of the intoxication The carbon monoxid affects the nerve-cells as well as the nerve-fibers (Sibelius), and yet we can hardly attribute the delayed symptoms to changes in the nerve cells alone They were not conspicuous in the case reported in this paper Delayed symptoms may depend in large measure on previous alteration of the vessels, as by age, and on the concentration of carbon monoxid in the gas breathed Most cases of severe mental disturbance, in old persons, have been of the delayed type (Sibelius)

[5] Sibelius Monatschr f. Psychiat u Neurol, [illegible] rg Heft.

Carbon monoxid causes fatty degeneration of the intima and muscular coat of the vessels of the central nervous system Sibelius attempts to give an explanation for the late symptoms, and attributes them especially to the alteration of vessels The vascular changes progress after carbon monoxid has been removed from the blood, and carbon monoxid does not remain more than a few days in the blood Wachholz, however demonstrated the gas in the blood in a fatal case seven days after the poisoning Sibelius thinks it is possible that from carbon monoxid poisoning several organs become affected, and that by imperfect elimination injurious metabolic substances are retained and affect the cerebral vessels In some cases the vascular changes are not progressive, but their results are progressive from continued imperfect nutrition Hemorrhages may occur and cause progressive symptoms, and yet hemorrhages have only occasionally been found Aside from these possibilities we must assume, according to Sibelius, a progression of the vascular changes, although we do not understand the method This I would explain, in part at least, by calcification Sibelius makes no mention of calcification, and I do not know that anyone else has done so The nearest approach to such an observation is by Poelchen In a case in which he examined the vessels, drawn out of the lateral perforated substance at the base of the brain, which supply the inner part of the lenticular nucleus, he found fatty change in the intima and muscular coat, and in the larger vessels the muscular coat was calcified, all other vessels in the brain were normal He does not mention calcification of the small vessels in the inner segments of the lenticular nucleus

Calcification of the capillaries has been found in different parts of the brain under different conditions, also in the globus pallidus by Wollenberg (cited by Obersteiner) It was very pronounced in the inner segments of the lenticular nucleus in the case of gas-poisoning described in this paper, and was present in milder form in the same region in the case to be reported with similar symptoms but without a history of gas-poisoning, although the failure to obtain any history makes the etiology uncertain In no reported case have I found mention of the deposit of calcium loose in the softened tissue or in the form of corpuscula arenacea, as in the case here described This calcification of the small vessels of the inner part of the lenticular nuclei is probably a progressive process and as it increases impairs more and more the nutrition of the areas supplied by the affected vessels It doubtless causes the progressive spasticity of the limbs, but it is difficult to explain the stupor from the limited lenticular lesions It is worthy of note in this connection that in the cases of the family form of softening of the lenticular nuclei reported by Wilson the mental condition seems to have been peculiar

I have sought an explanation for the formation of lime salts in the brain in Wells' "Chemical Pathology"[6] and find it stated there that in calcification the calcium salts come from the blood where they are held in solution or in suspension by the proteids, either as the carbonate and phosphate themselves, or as calcium-ion-proteid compounds, or perhaps both This suspension or solution is an unstable condition, possible only because of the extremely small proportion of calcium in the blood (about 1 10,000), and therefore capable of being overthrown by increased alkalinity of the blood, changes in the proteids or changes in the quantity or composition of the calcium salts

Retrogressive changes in the tissues are a sine qua non Hyaline degeneration, the chemical nature of which is not understood, is a very favorable condition, as also is necrosis when absorption is deficient

In the areas that are to become calcified the circulation is very feeble, the blood-plasma seeping through the tissue as though any dead foreign substance of similar structure, without the presence of red corpuscles to permit of oxidative changes

Calcification may be caused by utilization of the proteids of the fluids by the starved tissues so completely, because of its slow passage through them, that the calcium cannot be held longer in solution This idea has little support but has been advanced The possibility of the formation of calcium-binding substances within the degenerated area has always seemed more attractive, and has received the most attention by investigators

Following is the report of a case which presented the same clinical appearance as did the case of gas-poisoning, but the patient was brought into the Philadelphia General Hospital without any history, and nothing could be learned of his previous condition

Case 2 —F B, aged 70, was admitted Dec 22, 1911, and died Jan 2, 1912 He was stuporous although he answered questions at times when spoken to, but his speech was incoherent He muttered and sang in a low voice, he had no idea of place or time, was incontinent and said he heard and saw the Lord Later he could not be aroused. The right pupil was very much dilated, the left was contracted and irregular *They did not respond to light* There was rigidity of all the limbs, especially at the elbows The patient lay on his back with head and eyes turned to the right Both forearms, especially the left, were strongly flexed on the arms Extension of the forearms passively was difficult, and when the left was extended the patient screwed up his face as though in great pain Pricking the face with a pin caused no change in expression The lower limbs were slightly flexed at the knees but were more easily extended than the upper The man moved the right arm and both legs at times quite freely, but did not move the left arm—at least no voluntary movement of this limb was noticed The biceps and triceps reflexes were exaggerated The patellar reflexes were not obtained, probably because of the spasticity Plantar stimulation gave plantar flexion

Symmetrical areas of softening were found in the inner segments of the lenticular nuclei They were larger than in the case with a history of gas poisoning, and did not have exactly the same superior and inferior limits The small arteries in the areas of softening showed a moderate degree of calcification but corpuscula arenacea or other calcium deposits were not found

Dana[7] probably was the first American writer to call attention to the bilateral softening of the lenticular nucleus in gas-poisoning The cases described in our report are especially interesting in connection with the extraordinary cases of progressive degeneration of the lenticular nucleus of the family form, described by S A K Wilson[8] It appears that when the lesions are confined to the lenticular nuclei intense spasticity is produced with apparent paralysis, but power of voluntary motion is really retained, although all movements are awkward and are of less power

I am indebted to Dr A J Smith for the photographs

SAFETY-RAZOR-BLADE SCALPEL

JOHN B MURPHY, A.B, M.D, LL.D
CHICAGO

Every surgeon has more or less often been annoyed by a dull scalpel when a sharp one was very much desired. Furthermore, after a few strokes of the scalpel, especially when made in a firm or resistant tissue, like an old scar, the cutting edge of the scalpel becomes dulled Sharpening scalpels is a nuisance and at best very unsatisfactory In order to overcome these objections, I have devised some handles to carry the two types of safety razor blades most commonly used After these blades are no longer serviceable for the purpose for which they were intended, they make excellent scalpels They are cheap and easily obtainable

The accompanying illustrations are self explanatory The ordinary scalpel handle is provided with two arms, united above but not below, between which the knife blade is inserted To carry the double edged blade, one arm is provided with two stubs which fit into the two perforations in the blade, so as to hold the blade firmly, and a thumb ratchet locks the arms, thus making a splendid, double edged cutting instrument (Figs 1 and 2, *A*)

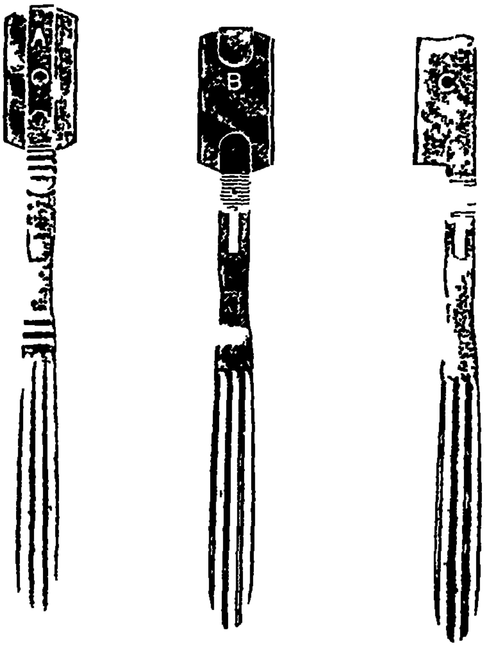

Fig 1—Three styles of handles *A* is used for a double cutting-edged blade *B* is provided with the flange which is visible on the right hand edge of the blade *C* is the single cutting-edged razor blade handle.

A second type of handle has the carrying arm provided with a broad flange which protects one cutting edge so that a single cutting edged instrument, like the ordinary scalpel, is obtained This scalpel handle has only one arm, which is turned down over the blade on top The thumb ratchet when pushed up secures the blade below (Figs 1 and 2, *B*)

The third type of handle is intended to carry a single cutting edged blade, like the auto strap razor blade It is constructed like the second style of handle except that it has no flange on the carrying arms and is not provided with stubs, this blade having no perforations (Figs 1 and 2, *C*)

I have used these scalpels for some time in all my work and have found them very serviceable and satisfactory

104 South Michigan Avenue.

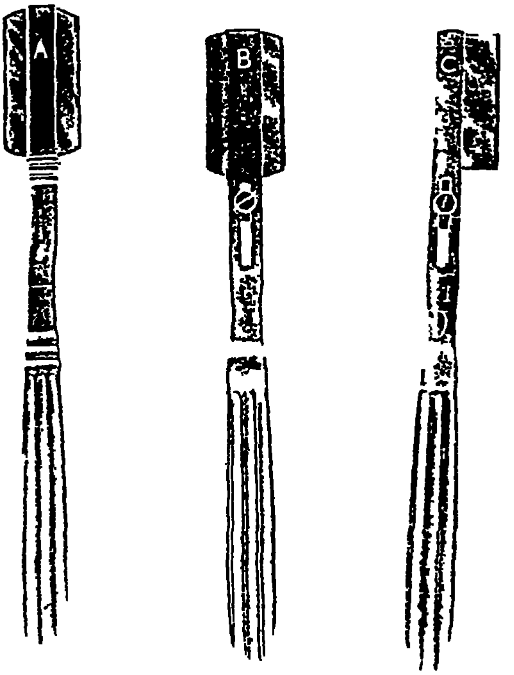

Fig. 2—Reverse of the three handles The flange on *B* is now seen covering the left half of the blade.

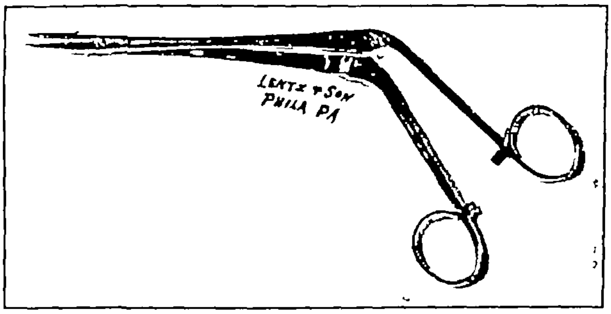
CLEFT PALATE NEEDLE-HOLDER

GEORGE M. TODD, M.D
Visiting Surgeon St. Vincent s Hospital
TOLEDO, OHIO

Much of the difficulty of placing sutures in cleft palate operations may be obviated by the use of this special needle holder In operating with the child in the head down position, using the ordinary needle holder, vision is obscured by the hand being between the field of operation and the eye By the use of a needle holder constructed with the hand portion at an obtuse angle, as shown in the illustration, this difficulty is overcome. The surface of the palate is plainly in sight at all times, and the sutures are readily placed in position.



Cleft palate needle-holder

The holder, in addition to its angular shape, has a notch on one blade into which the other blade passes when the holder is closed This prevents any [illegible] and secures firmness The needle bite is small, [illegible] work intended [illegible] the size of the needle [illegible] a catch finger holds to fasten the [illegible]

AVERAGES IN ATTITUDE AND TRUNK DEVELOPMENT IN WOMEN AND THEIR RELATION TO PAIN*

ROBERT L DICKINSON, MD
AND
WALTER TRUSLOW, MD
BROOKLYN

PART I THE MECHANISM OF THREE TYPES OF POSTURE, VIEWED FROM THE SIDE, BY DR TRUSLOW

Three types of posture, varying according to differing anteroposterior relationships, are here named and discussed (1) "kangaroo" type, (2) normal or neutral type, and (3) "gorilla" type

Distinguishing features of the normal type are (1) the line of gravity of the body passes through important pivotal points, (2) the pelvis is balanced in equilibrium on the heads of the femora, its position being indicated by the angle which the plane of its inlet makes with the horizon, (3) this relation of important pivotal points with the line of gravity and this balance of the pelvis insure an easy balance of all superimposed structures of the body, including the spine in its physiologic curves, (4) the rear perpendicular touches two points, the shoulders and the buttocks (Fig 1)

The carefully balanced segments of the body are retained in position by nicely balanced muscle forces In this normal position, the internal organs of the trunk are placed in proper anatomic relation to each other The position therefore conduces to normal visceral activity

Anteroposterior deviations from the well-balanced position of the normal type tend toward (1) mechanical instability, (2) muscle and ligament strain and pain, and bone deformity, (3) abnormal relationship of the viscera of the trunk and therefore toward derangement of their function

These deviations mainly tend toward two opposite types, which are called respectively the "kangaroo" and the "gorilla" types (Figs 2 and 3)

There are other etiologic factors, but this paper is limited to pointing out the relation of the *corset* and the relative *height of heel* to the two variants from the normal in posture

In the accompanying cuts and in the complete paper the three types are compared segment with segment, noting in each mechanical relationships, muscle and ligament equilibrium of strain, and pain and visceral relationship Treatment is outlined from the standpoints of correction by mechanical support—corsets and shoes—and by prescriptive exercises The question of other methods of treatment of the abdominal and visceral ptoses is not here discussed

The "kangaroo" type of posture conduces to strain on and pain or aching of the low back muscles, and of the muscles back of the knees and of the calves The posture favors the forward-carried abdomen and pelvis, and thus forward displacement of their viscera Sacro-iliac joint strain is not infrequent This position tends toward weakening of the long (plantar) arches, but relieves strain on the metatarsal arches of the feet

In the neutral position there is no mechanical tendency toward the abnormalities outlined Pathologic conditions may here cause, as in the other conditions they may modify, the strains elsewhere mentioned, but this posture does not cause them

The "gorilla" type of posture favors strain and pain of the upper back muscles, iliopsoas muscles or of the sacro-iliac joint structures (which may easily be mistaken for low-grade pelvic inflammation, etc) The position is very liable to cause metatarsalgia or pains

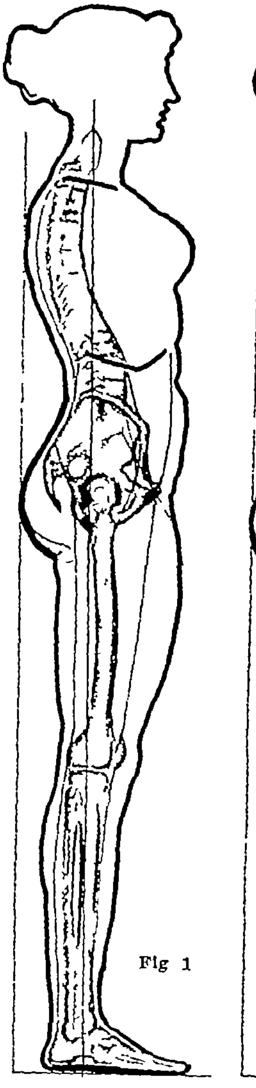

Fig 1

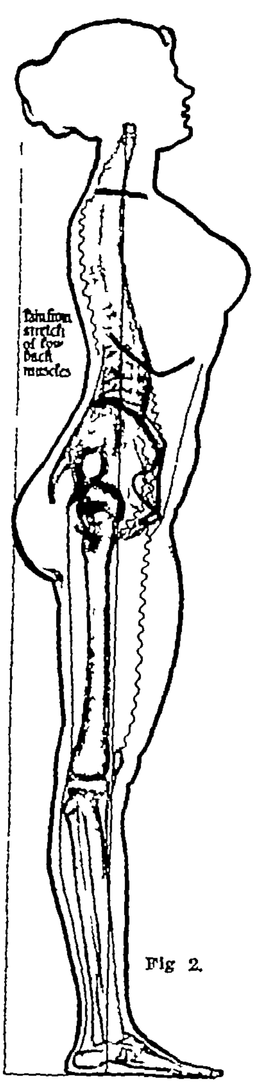

Fig 2.

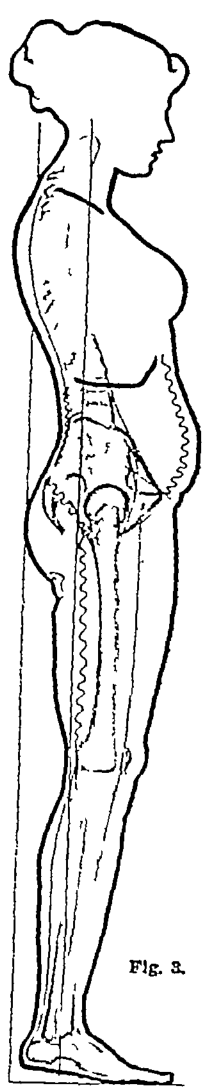

Fig. 3.

Fig 1—Normal or neutral type of posture Distinguishing features are (1) Line of gravity of body passes through important pivotal points (2) the pelvis is balanced in equilibrium on the heads of the thigh bones, (3) this relation of important pivotal points with the line of gravity and this balance of the pelvis prevents muscle and ligament strains and (4) the rear perpendicular touches the middle back and the buttocks

Fig 2—Kangaroo type of posture Distinguishing features are (1) Most pivotal structures of the trunk are carried in front of and those of the lower extremities behind the line of gravity (2) the pelvis rotates forward downward (3) the forward carried trunk puts strain on the spinal and pelvospinal ligaments and muscles and tends toward forward displacement of abdominal and pelvic viscera Wavy lines indicate muscles relaxed dot and dash lines show muscles in action

Fig 3—Gorilla type of posture Distinguishing features are (1) Most of the pivotal structures of the trunk are carried back of and those of the lower extremities in front of the line of gravity (2) the pelvis rotates backward downward (3) the backward carried trunk puts its own variety of strain on the spinal and pelvospinal ligaments and muscles and tends toward backward and downward displacement of the abdominal and pelvic viscera Wavy lines indicate muscles relaxed dot and dash lines those in action

in the fore part of the foot Especially is this the case if high heels are worn

---

* Read in the Section on Obstetrics and Gynecology of the American Medical Association at its Sixty Third Annual Session held at Atlantic City June 1912

* Because of lack of space this article is abbreviated in The Journal. The complete article appears in the Transactions of the Section and in the authors reprints

The mechanical treatment of the kangaroo type includes a corset, which shall make strong circumferential pressure on the pelvis, and shall have ascending lines which shall shift the trunk backward (Fig 4) Moderately high heels, to relieve "knee-back," may at first be worn Gymnastics must tend toward posture training and toward special development of abdominal, buttock and calf muscles For the gorilla type, the corset must have strong pelvic pressure and must have lines which shall carry the trunk forward (Fig 5) A sacral pad will help this The heels must be lowered as quickly as possible and special foot-braces, with metatarsal arch support, are often necessary The exercises aim toward posture training and toward the development of scapulovertebral, abdominal, anterior thigh, calf and toe flexor muscles

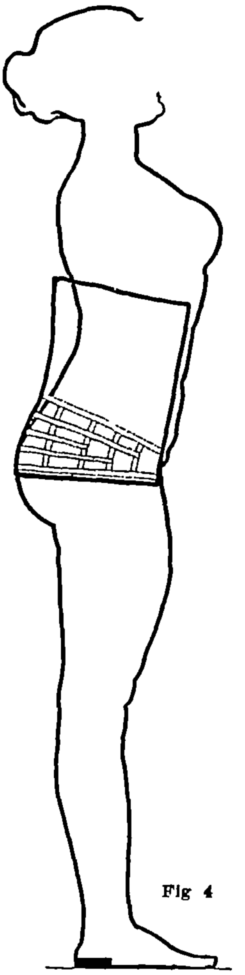

Fig 4

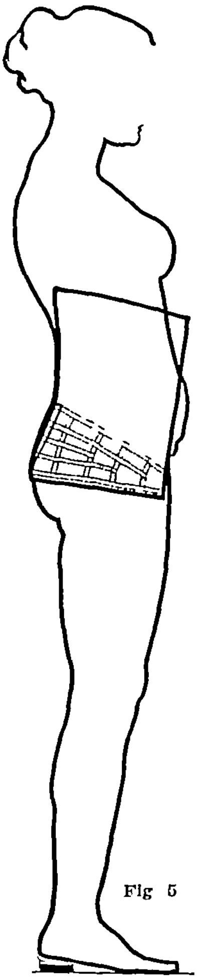

Fig 5

Fig 4 —Mechanical treatment of kangaroo type The corset is tight or even reinforced about the pelvis and its lines are such as to hold trunk backward The heels may be moderately high to relieve the strain of knee-back.

Fig 5 —Mechanical treatment of gorilla type The corset is tight about the pelvis and its lines are such as to hold the trunk forward The heels are lowered to carry knee balances backward and specially padded soles are placed under painful metatarsal arches

This preliminary study of the mechanism of three types of anteroposterior posture takes cognizance of the valuable work of Goldthwaite, Reynolds, Lovett, Dickinson, Franklin Martin and others It could well be supplemented by more in the same direction and by studies of variations from the normal, due to lack of lateral balance

In conclusion, this paper points out the mechanical instability of habitual body-carriage in front of the line of gravity and to the rear of this line, it draws particular attention to trunk, sacro-iliac, knee and foot strains, it shows the relation of corsets and of heels to these, and outlines principles of mechanical treatment by correcting corsets, proper foot support and by prescriptive exercises

PART II AVERAGES IN ATTITUDE AND TRUNK DEVELOPMENT IN WOMEN, AND THEIR RELATION TO PAIN, BY DR DICKINSON

How many clinicians strip patients standing? He who does not misses the chance to detect the source of many an ache Loath as we must always be to subject women — particularly those of sensitive English and American up-bringing — to the distress of this procedure, the time will come when no [illegible] will consider himself careful or thorough [illegible] causes of chronic pains about the [illegible] carry on

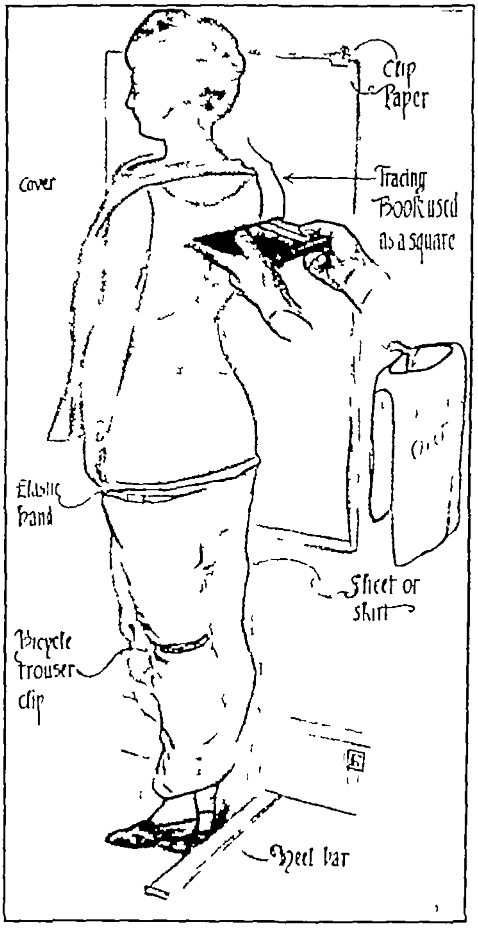

Fig 6 —Simple office method of taking outlines of the figure The subject stands against a heel bar on the floor the bar being pivoted to swing out of the way when not needed and always swinging back to the same mark The clips that hold the paper are fixtures the edge of the paper hangs to a mark on the wall or against a drawing board (which should run to the floor) In this way accurate comparisons may be made with past and future conditions because the paper will always be in the same relative position to the heel bar A narrow book that acts as a square is held in both hands in its groove a soft pencil or crayon is caught in place by elastics and with this pencil the profile is followed and the tracing made The sheet held snugly by hip garter and knee clip exhibits the knee action The whole is more exact, simple and speedy than photograph or shadow tracing

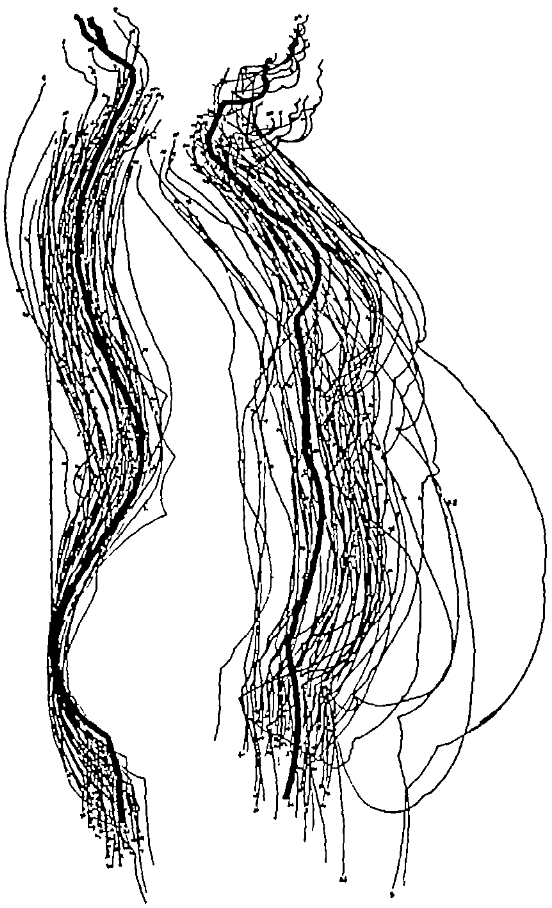

Fig 7 —A group of forty seven tracings superimposed in order to study averages and extremes The average shoulder is in fair relation to the buttock the average chin is forward breast pendant, abdomen thick prominent sagging—whether children have been borne or not—the buttock long and low Hundreds of the authors tracings multiply the same lines Heavy black line normal (antique)

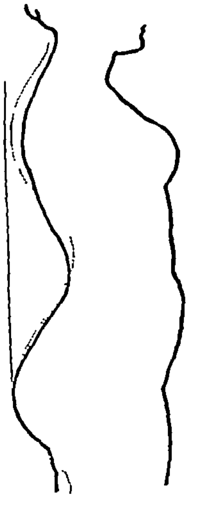

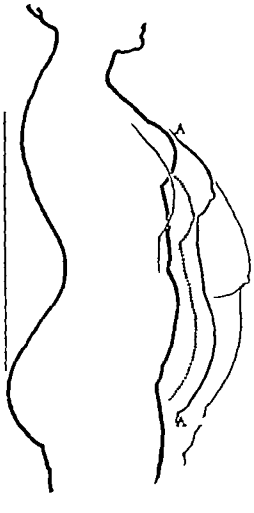

Fig 8 —While the average back in the scapular region nearly approaches the perpendicular from the buttock the droop forward of the neck brings an excessive curve in this region which produces a round shouldered effect that is a general tendency to the gorilla type of back Dotted line the average

Fig 9 —Anterior lines of the trunk The breast drags downward in nearly every instance Along the abdomen the dotted line and the heavy black line A show the most common averages according to the previous occurrence of pregnancy or not. This average anterior abdominal line which is strikingly in advance of the normal (heavy black) line shows greater prominence at its lower portion. This is the main average deformity of women.

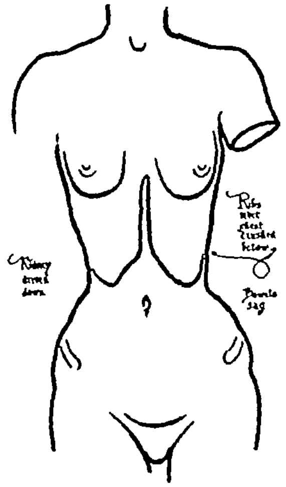
such observation as one of the regular details of a systematic examination[1]

The average civilized woman sags The average back is nearly upright The shoulders run only slightly toward rounding, and the chin to drooping The deformity which is practically constant is protrusion of the abdomen Relaxed from poor muscle, pushed out by low-hung inner organs, and padded with fat, mostly below the navel the anterior abdominal wall is in advance of the normal, 1 inch in a large group and 2 inches in yet another large series The breasts drag down and the buttocks sweep low Most hips and thighs show fat pads, but these, like the abdominal adipose, are local deformities and not part of a general obesity



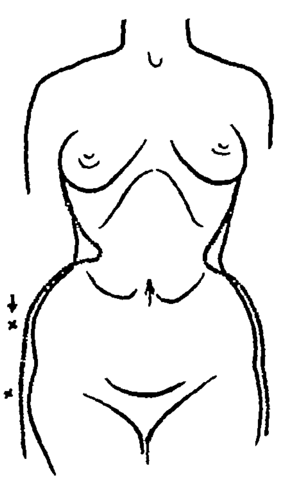


Fig 16—Congenital deformity accentuated by corsets The long trunk type suffering from constriction during period of growth The angle between the cartilages of the ribs does not admit the finger kidneys and bowels hang low

Fig 17—Hip-pad and thigh pad produced by the corset the chorus girl' figure. Extreme instance of deformity produced by hour-glass corset Between hip-pad and thigh pad the newer form of corset by its high pressure pelvic girdle, is producing a second waist line indicated on the right of this patient

Drawn from a large number of cases my tracings show not only the frequency of the defects listed above, but the persistent presence of faulty muscles all about the waist line, and a very constant narrowing of the chest and of the angle in front, between the cartilages of the ribs

Among postures, one-third were found good, one-half defective Certain types of body form are particularly susceptible to defective carriage and defective corsets, such as the individual with the long and slender trunk, and the overfeminine figure

The corset may be tolerated, except during active exercise, if neutral[2] Corsets other than harmful are not much in evidence The hourglass form, with its pressure mainly at the waist line and its downward drive, was determined to be still the average design, being found in fully two-thirds of the cases studied In one-half the cases all pressures ran high The spring or gap of the corset when unhooked — the most convenient measure of amount of constriction — should not exceed 2½ inches The tight corset harms vigorous women little, weaker women, greatly But there is no substitute for Nature's corset — the well-set-up anterior abdominal wall

The remedy lies in thoroughness in examination, particularly among women with backache and enteroptosis and neurasthenia, in muscular training continued after the year it is usually abandoned — the fifteenth — and systematically ordered after labor, and in the supervision of gymnastics and of dress

We have advocated stripping, at least to the union suit, or to the cape shown in Figure 6 To avoid delay in office work a dressing-room, however small, is desirable, to avoid criticism, a nurse or attendant is advisable, though not essential, to save disappointment, results should not be promised except in terms of months and with the understanding that defects of attitude and atrophy and pressure are but one of the causes of the ache and weakness The secret of success is persistence, and no more difficult task presents itself to the practitioner than the remodeling of the muscular habits of the flabby and obese or the self-indulgent Printed slips or typewritten sheets of instruction concerning exercise and carriage, a diary or daily notes to be submitted to the physician at stated intervals, somewhat after the manner of the sanatorium inquiry, showing what has been done daily in the number of exercises, cold sponging, and regulation of nutrition—all these are essential to results

The eye, once having been led to look for trunk defects, becomes trained to see them quickly, especially if a few of these have been traced in order to develop the powers of observation, or the office attendant may be trusted to draw attention to many of these matters It is the old question of thoroughness versus superficiality — of a patient hunt for less obvious causes

ABSTRACT OF DISCUSSION

Dr Robert B Osgood, Boston The question as to whether a fairly vicious corset has any marked immediate effect on the position of the organs, especially the stomach, has interested me Two x rays of a young woman of 20, in good health and without symptoms, were taken one directly following the other after a bismuth meal, both in the stand ing position The first shows the lower border of the stomach at the level of the umbilicus The second, after putting on the corset, shows the stomach crowded upward almost 10 cm One can easily imagine the extent to which the organs below the hour glass corset constriction must be crowded down and a sagging stomach or colon be made still more ptosed and there retained. The question at once arises as to what effect attitude alone has on the causation of back pain Of 130 tracings of a college class taken alphabetically 53 per cent showed bad postures and 47 per cent neutral or good Of the faulty attitudes, 4 per cent could be classed as kangaroo and 49 per cent as gorilla The lumbar lordosis was increased in 17 6 per cent and diminished in 9 per cent and considered to be within normal limits in 73 4 per cent It would seem that faulty attitude may exist, at least for a certain time, without necessarily giving rise to subjective symptoms of pain, when we consider that while 53 per cent showed a bad position of standing only 5 per cent had pain The prevalence of faulty attitudes in women is suggested by this series In 760 cases of low back pain in the clinic of the Massachusetts General Hospital 70 per cent of patients were men Of course, some of these were traumatic but a large number were classed as attitudinal. Since so large a proportion were men, the corset alone cannot be responsible I think we must consider the exact localization of the pain in these cases of static back or postural strain as still somewhat *sub judice* That a constant strain on the lumbar muscles may induce pain referred to their insertions and attachments seems entirely rational and undoubtedly explains the pain in many cases when these faulty postures become constant There would seem also to be strain on the sacro iliac joints, pivotal as they are In women, following childbirth, we are familiar with the train of symptoms which their continued relaxation sometimes produces, and when we can appreciate tenderness to deep pressure localized over the posterior sacro iliac ligaments and can cause pain by motions which strain these joints alone, I believe we may suppose strain of these joints to be a cause of pain Certain it is that treatment directed to the protection of these joints relieves the discomfort

AFTER-RESULTS IN TUBERCULOUS PATIENTS TREATED DURING THE YEARS 1891-1911 AT THE SHARON SANATORIUM *

VINCENT Y BOWDITCH, M D
BOSTON
AND
WALTER A GRIFFIN, M D
SHARON, MASS

This paper is the result of an investigation of the present condition of patients discharged from the Sharon Sanatorium from the time of its foundation in 1891 to Jan 1, 1911, that is, no patient will be reported who has not been away from the sanatorium at least one year

In the nineteen years thus covered 592 patients have been discharged Of these, twenty-two stayed so short a time that they were considered not treated Nine others were admitted for some other complaint than tuberculosis of the lungs Twenty-four did not react to tuberculin and were termed merely suspected cases Seventeen in the early years of the sanatorium were discharged as well, this term being used, it may be, because at that time there had been no definite rules formulated by a nomenclature committee These seventeen patients also are not considered in this report, since in practically all instances they were admitted with the diagnosis of phthisis questioned, or as having bronchitis, and received no tuberculin test This leaves 520 patients, of whom forty-eight were discharged as "not improved," 175 as "improved" and 297 with the disease "arrested" or "apparently cured"

Of the forty-eight non-improved, all died as might be expected, a mortality of 100 per cent Of the 175 discharged as improved, 107, or 60 per cent, died, in fifty-one, or 29 per cent, the condition is reported good, and seventeen, or 9 per cent, have not been traced Some of the improved patients have continued in a very gratifying condition of health, and frequently they have arrested their disease and have taken up their life-work again The following history is fairly typical

Case 190 —This patient, without any family taint of tuberculosis or previous severe illness, had had a cough for a year following an acute cold She presented on examination well marked dulness with harsh respiration at both apices, especially the left Numerous fine and medium moist râles were present over the upper half of the left side front and back and at the extreme lower base The sputa showed tubercle bacilli The patient stayed ten months in the sanatorium and has remained in excellent condition for ten years except for an attack of appendicitis which required operation She was a professional singer and has taken up her work again, holding a position in a large city church

In 1902 a report was made of seventy-nine patients with arrested cases treated at Sharon Sanatorium[1] Of these, six, or 7 5 per cent, have not been heard from recently, and twenty-two, or 26 5 per cent, have been reported as dead This leaves at least 66 per cent of this series of patients still living after ten years, and perhaps a higher percentage, if some of the six who have not been heard from could have been reached Practically all of the 66 per cent report that they are in good physical condition, and many of them are wage-earners The following case may be cited in illustration

Case 49 —Two brothers and two sisters of this patient died of consumption Two months before entrance she had a sudden hemoptysis of fairly large proportion Examination showed dulness in the middle of the right back with fine râles Tubercle bacilli were numerous in the sputa The patient was discharged in 1894, seventeen years ago, and has remained well although her work has been hard as a domestic in Boston, until about a year ago when she married and returned to her old home in Ireland

As before stated, we have at this time 297 arrested and apparently cured cases to report All which received the latter term (forty-four) would have been considered arrested cases according to the previous method of tabulation, and for the purpose of this paper we shall consider them as arrested cases From this point of view it is only fair to say, however, that "arrested" used to mean more to us than the present use of the term allows, for if tubercle bacilli were present at the time the patient was discharged, the term "improved" was formerly the most favorable one used On the other hand, in the early years of the sanatorium a case was frequently called "arrested" after a shorter period of residence, even though at times only a little over a month had elapsed Such patients had lost cough and expectoration, if any, almost immediately after entrance They had learned the regimen of the sanatorium and had good home environments In practically all such instances the after-results have justified the expectation expressed by the term According to the present nomenclature, however, certain patients have gone out as "improved" because of residence limited to less than two months Numerically, such cases have been as many as those which, with tubercle bacilli still persistent at time of discharge have been called "arrested," according to the present use of the term, so that for the purposes of comparison with previous reports we have counted together the cases of arrest and apparent cure and called them arrested

---

* Read at the Annual Meeting of the American Climatological Association at Hartford, Conn., June 1912.

[1] Tr Am Clim Assn 1903, p 64

Of the 297 cases so classed, twenty-five, or 8 per cent, have not been traced, and thirty-five patients, or 10 per cent, have died, leaving 237 patients, or 81 per cent., known to be alive and for the most part in excellent health

In arriving at a diagnosis nearly all patients since 1902 who have not shown tubercle bacilli in the sputa have been tested with tuberculin before being pronounced tuberculous This has been done to avoid the criticism which could be advanced with some justice that occasionally patients without tuberculosis might have been discharged, thus bettering the reported results of the sanatorium Each year there are three or four who are sent out as "suspected" cases, but without taint of tuberculosis as ascertained by the test It might be said, however, that all of these could at least be classed under the frequently heard but erroneous term "pretuberculous," that is to say, these patients are always debilitated and in a condition to be attacked by disease The sanatorium care and regimen is therefore a good thing, for it teaches such patients how to care for their physical condition so that they are not so liable to any disease

In our opinion the administration of the tuberculin test is not to be lightly undertaken We remember one rather harrowing experience which it may prove of interest to recount

Case 206 —Two years before entrance, this patient had a cough for about three months She afterward began training as a nurse and the chest was examined by chance by one of the visiting physicians, although there were no symptoms referable to the chest at that time. She had dulness over the upper half of the right lung and medium and fine râles all over this side As there was no sputum for examination, she was given 0 002 gm tuberculin about two weeks after entrance This caused a slight reaction, and as the patient seemed all right she was allowed to stay up the next day The temperature, however, went up a little on that day and the two days following The patient was again put to bed and was kept there for nearly eight weeks before she could be safely allowed about A part of this time the temperature varied between 100 and 103 at night, and cough, which had been absent up to this time, became troublesome, the sputa containing many tubercle bacilli. This upset naturally worried us a good deal, but on further investigation it was found that on the two or three days after the test the patient overexerted herself walking, so that the upset was ascribed to this as much as to the tuberculin After discharge this patient again took up nursing and remained in good condition for several years She finally died of an acute hemorrhage nine years after discharge

Since this case we have been more hesitant in applying the test to patients who present signs of persistent active catarrh in the lungs, and one or two instances usually occur each year in which we consider a patient to be tuberculous because of the history and certain suspicious signs in the chest even though no tubercle bacilli are found and no tuberculin is given The following would be a rather typical case of this sort

Case 532 —The father and mother of the patient had died of tuberculosis about one and one half years before the patient's entrance The patient had had what was called 'grip" with occasional cough Recently there had been no cough or expectoration The chest showed marked dulness over the upper half of the right side and at the apex on the left Breathing was harsh on the right and the voice was bronchophonic Medium and fine râles were heard in plenty over the dull areas The throat showed general congestion with a small ulceration on the left, the true vocal cord and both false cords were red and swollen The patient had been hoarse for a year At no time was any sputum available for examination Such a case certainly needed no tuberculin to prove that treatment was necessary, and the administration of a test dose might have had disastrous results

In obtaining the results nothing new or original has been used in treatment The trinity of fresh air, good food and rest have been the main reliance About four years ago an experiment was made with a sleeping-out balcony The five patients who were on this balcony did so well and were so enthusiastic that other balconies were made, until now every room has a large door through which the bed may be wheeled on to a veranda All the patients favor sleeping out and if, for any reason, the weather forces them to remain with half the doors closed there is a general complaint of stuffiness and lack of air, even though under such circumstances there is better ventilation than in any ordinary room We have concluded, therefore that even though we cannot say in any individual case that the patient is better for sleeping out, still we feel that, all things considered, the condition of patients is so much bettered that the expense of making the balconies has been justified

In forty-two cases tuberculin has been used therapeutically For the most part these were not especially favorable cases, in fact, nearly half (nineteen) were considered moderately advanced and there were only four patients who were free from tubercle bacilli in the sputa Of these four the signs in two extended over more than half of each lung One of the others, who had a history of hemoptysis, had definite signs in one lung which have persisted to the present. The other patient had a tuberculin reaction and was given treatment because her home environment was poor and it was desired to give her as much resistance as possible Seven of the forty-two patients have died Four of these were treated in the first years of our use of tuberculin and would not at present have been chosen for such treatment, since they were evidently fast failing, and showed elevation of temperature and rapid inroads of disease Another of the seven who have died wore herself out needlessly by too much traveling contrary to advice, and one had a sudden hemoptysis One patient who had tuberculin treatment has not been traced This leaves thirty-four of the forty-two cases, or 83 per cent, in good condition This seems to us a good showing, considering the relatively poor condition of many of the cases, and we therefore favor the use of tuberculin in cases of open tuberculosis without fever and, theoretically at least, we believe that it is indicated in closed cases as a means of conferring something of an active immunity Before leaving this phase of the subject it would perhaps be of interest to touch on the history of the first patient who received the treatment at the sanatorium and who has done so well for eight years that we have at times felt like giving tuberculin to all patients as a routine

Case 243 —This patient was first admitted April 20 1903 There were well marked signs all over the left side of the chest and at the top of the right side The sputa contained many tubercle bacilli With ordinary sanatorium treatment the cough and expectoration ceased and she was discharged at the end of eight months Within six months the patient was back again with a renewal of all the old symptoms With the same treatment she [illegible] d [illegible] she gained a little in the next five mo[illegible] of radi ment. Finally she was given tuberculin over a period of five months in doses ranging from 0 0005 gm to 0 6 gm At first the cough and expectoration increased, but soon the condition began to improve and for more than a month before the patient was discharged the symptoms were entirely absent and the physical signs showed much improvement After discharge she worked for a time in a bleachery without breaking down, at present she is a waitress in a summer hotel and reports that her health is excellent, eight years after the use of tuberculin

In considering again the results of treatment in this series of cases, one cannot but be impressed with the after-condition of the arrested cases as compared with that of the improved cases—health being reported good in 81 per cent of the former and in only 29 per cent of the latter The oft-repeated moral is again brought forcibly to mind by these figures, that in order to give patients the best chance for recovery and for subsequent usefulness in life, they should be treated at an early stage while yet the disease may be arrested We have learned that patients are practically never cured during residence at a sanatorium, they are merely started in the right direction It is fairest to them, therefore, to begin treatment at a stage when they may be given the best chance to regain health

In reviewing the work accomplished in the last twenty years, we feel that our attitude has been one of conservatism in regard to the results obtained When one reflects on the condition of affairs in the treatment of tuberculosis twenty or twenty-five years ago, and recalls the sense of hopelessness that was felt whenever a patient presented himself with symptoms of pulmonary disease, especially among the less favored classes, we feel that we are justified in looking with great satisfaction—even enthusiasm—on the work of twenty years at the sanatorium

It is often impossible to impress on others by figures alone facts which through long years of experience stand as positive proofs to us of what we wished to obtain It was never believed or even hoped that sanatorium treatment alone would eradicate tuberculosis, but it did not take long to convince us that it was a great step in the right direction and that infinitely more could be done than heretofore to bring people back to health, even under what had been considered in former years most unfavorable conditions

In stating our results, it must be remembered, too, that in using the term "arrested" we have applied it to the results obtained in many cases in which at the beginning of treatment the physical signs and symptoms of disease were well marked, and in spite of which condition a successful result was often obtained for a number of years The surprising part has often been that such patients have remained so long without relapse on resuming the ordinary conditions of life

To those who have been closely connected with the work, the fact that has been of far greater influence than the mere collection of figures, although these themselves have given us the greatest satisfaction and more than we had dared hope for in former years, are the faces and general aspect of patients who on reunion days at the sanatorium appear to give their tribute of gratitude for help which they have received in former years The evidence that these persons give, not only of the good done to themselves, but of their influence on others in teaching methods which tend to prevent disease, is the most gratifying part of all our work

We have no sympathy with the attitude, which happily is now lessened, that because sanatorium treatment has not proved to be a panacea it has therefore failed in its purpose On the contrary, with greater confidence than ever before, we feel it to be one of the great and *important factors to be resorted to in conjunction with* every other known method of combating the disease which still holds the highest place in the mortality list of the civilized world

THE ETIOLOGY OF BERIBERI

CARL LOVELACE, M D
PORTO VELHO, BRAZIL

In The Journal, some time ago, there appeared an editorial comment[1] on the sanitary work incident to the construction of the Madeira-Mamoré Railway, in the states of Amazonas and Matto Grosso, Brazil I take it, therefore, that a brief description of this work would be deemed of interest to physicians For this reason, and in order to give a side-light on my subsequent remarks, I venture to prefix my observations on peripheral neuritis in Brazil, with the following

THE MADEIRA-MAMORÉ RAILWAY

The Madeira-Mamoré Railway is 227 miles long It extends from the head of navigation on the Madeira River southward and upward to the navigable waters of the Mamoré River—from Porto Velho de Santo Antonio to Guajara-Mirim Except for the improvements made by the company, both of these formidable names locate mere spots in the Brazilian jungle The first train over the whole line was run on April 30, 1912

Porto Velho is situated in south latitude 8° 45′, is 300 feet above sea-level, has a rainfall of 90 inches per year, and a temperature range from 56 F in the cool June nights to 102 F in the hot September days It is on the right bank of the Madeira River, which at this point has an annual rise and fall of 45 feet The annual volume of water discharged by this river is about the same as that of the Mississippi Boats drawing 8 feet of water ply on it all the year, and ocean-going vessels of *7,000 tons come to Porto Velho every year during the* period of high water, from December to May

Three previous attempts to build this railroad were unsuccessful, because of the terrible rates of sickness and death among those concerned Mr Neville B Craig[2] has written a most entertaining volume describing one of these melancholy failures

WORK OF AMERICAN PHYSICIANS

The sanitary branch of this work has from the beginning, *in 1907, been under the direction of American* physicians employed by the contractors In 1910, Dr Oswaldo Cruz, Brazil's foremost sanitarian, visited Porto Velho, sojourned here three weeks, approved the work then being done, and urged the compulsory administration of daily prophylactic doses of quinin to all employees not protected by screened houses In a non-military organization this has been found impossible to carry out perfectly, but even its partial enforcement has been of untold benefit Without the powerful influence and personality of Dr Cruz the liberty-loving Brazilians would have rebelled against this regulation

In 1911 the number of employees was about 5 000 comprising, approximately 250 North Americans 2,000 Brazilians, 1,000 Spaniards, 750 Greeks and 1,000 others, representing practically every country in the world The number of physicians at this time was nineteen of whom eighteen were Americans In all, forty physicians have been employed, of whom thirty-six were American, two Brazilian, one Spanish and one English

---

[1] Sanitary Work in Brazil Good Health a Commercial Asset, The Journal A. M A. Sept 24 1910 p 1120

[2]. Craig Neville B Recollections of an Ill Fated Expedition

The sanitary measures adopted have consisted in the provision of screened houses for all employees of the higher grades, in antimosquito campaigns in and about the permanent camps, that is, camps destined to become towns, in the compulsory, prophylactic administration of quinin to employees, in the regulation of food and water-supply, in the usual measures against the so-called quarantinable diseases, in attention to disposal of garbage and sewage, and, finally, in the prompt hospitalization of all except slight cases of illness

The nearest city and base of supplies is Manaos, where, for many years, yellow fever has been rampant On seventeen occasions cases of yellow fever have been brought to Porto Velho by the river boats, and last year a number of employees contracted the disease at the old town of Santo Antonio, 3 miles from Porto Velho We have been able to prevent the disease from getting a foothold anywhere on our line of work, only three cases having occurred in which the infection did not originate outside of our zone

Malaria, yellow fever, blackwater fever, bacillary dysentery and beriberi are the chief tropical diseases with which we have to contend We have had one rather sharp outbreak of typhoid fever, and lobar pneumonia has killed more than 200 of our employees The hospital consists of six detached wards with a normal capacity of 250 beds, an operating-room, a clinical laboratory, a post-mortem room and the necessary out-buildings We do autopsies on the bodies of all persons dying in the hospital The material is only too plentiful In addition to our employees, we receive a number of patients from among the *seringueros* for hundreds of miles around From Jan 1, 1908, to Jan 1, 1912 there were admitted to the hospital of this company 30,430 patients

DESCRIPTION OF A FORM OF PERIPHERAL NEURITIS

Among the 30,430 admissions to the hospital of the Madeira-Mamoré Railway between Jan 1, 1908, and Jan 1, 1912, the diagnosis of beriberi or of "polyneuritis" or of "multiple neuritis" was made 963 times The affection is known locally as *polynevritis,* and following the teaching of the celebrated Brazilian physician, da Silva Lima, a goodly portion—in North Brazil, a majority—of the profession affix the word *palustre* They regard the affection as a multiple peripheral neuritis incident to malarial infection Oswaldo Cruz himself shared this opinion until his visit to this hospital in the summer of 1910

Symptoms—Few diseases present such a variety of clinical aspects The onset may be sudden, the course swift and tragic We have a number of charts of intelligent patients with clear histories, in whom the duration of the disease from its very first symptom up to death by cardiac dilatation occupied less than one week On the other hand the onset may be so gradual and the symptoms so poorly defined that the disease is well advanced before the patient seeks relief Some recover in a few days, others are bedridden for months Some are waterlogged from the beginning, in others there is little or no edema In some the affection throughout seems to be entirely cardiac in others the heart appears to be absolutely unaffected even though the paralysis be extreme The deep reflexes may be lost as a first manifestation of the disease, quite frequently they are markedly exaggerated not only in the beginning of the disease, but also throughout its course and immediately before its fatal end They may be exaggerated to-day, and absent a week from to day

Sometimes the pain, particularly in the legs, is excruciating, more often the legs feel dead with vague, slight pains, or the "pin-and-needle" sensation A patient may enter the hospital to-day with no symptoms save the subjective ones of pains in his legs, and in forty-eight hours have become so edematous as to be almost unrecognizable The pain may be chiefly substernal, or in the thighs, or in the forearms It may be entirely absent

Death may come with dyspnea, cyanosis and a feeble, fluttering pulse, while the patient seems yet robust or it may come as a terminal dysentery or pneumonia after he has been exhausted by many weeks of suffering

Clinical Classification—What one may take as the type of our patients presents himself for treatment complaining that his legs are swollen and that his calves are sore and painful One finds on examination a rapid heart frequently with the pauses equal, and sometimes with a reduplication of the second sound over the pulmonic area, edema of the legs of maximum intensity over the pretibial area, knee-jerks usually exaggerated, but frequently lost, and areas of tenderness on the legs, giving rise to the "stiff" gait, with or without areas of anesthesia and of paresthesia Fully three-fourths of our cases present these symptoms and these alone The tachycardia may be slight and may not be noted unless one makes the patient walk about The arhythmia may be absent Edema is present at some time in perhaps 90 per cent of all cases Pain in the legs, especially the calves, and in the thighs, particularly along their internal and posterior aspects, is also a fairly constant feature

Patients of this group—and it comprises 75 per cent of the total—usually recover on being put to bed and given an easily digestible diet, with treatment of any associated malady as malaria or uncinariasis A few, however, grow progressively worse in spite of any and all treatment

The severe cases fall into two groups (1) those in which symptoms, apparently cardiovascular, dominate the situation, and (2) those in which paralysis of various groups of muscles, with pain and tenderness along the nerve trunks, is the characteristic feature To the former of these two groups belong the acute pernicious cases characterized usually by anasarca and a rapidly developing dyspnea, cyanosis and death

Any case may at any time develop these pernicious symptoms Even in these fatal cases the edema may be slight Sometimes the patient dies suddenly of heart failure after he has so far recovered, apparently, as to have been allowed to sit up

A striking and cheering feature of a proportion of this group is the rapid recovery which begins on the institution of rest in bed and good nursing

Our severe cases of the paralytic or atrophic type fall clinically, also, into two classes (a) a smaller group with a rapid onset of paraplegia, and (b) a larger group characterized by the slow development of paralysis, by some sensory disturbances and by extreme chronicity These are the cases which accumulate in our wards and overcrowd them, unless they are invalided away

A man may walk into the hospital with a mild tertian infection, which yields promptly to quinin He has experienced nothing beyond the usual phenomena of a malarial attack, save, perhaps, unwonted feeling of weakness in his legs. He is surprised to find that after the subsidence of the fever, his legs become weaker instead of stronger, until in a few days or weeks he is unable to stand. His heart may apparently be unaffected. He has no pain. The blood and urine are negative. Usually, but not always, there is edema of the legs. The knee-jerks are lost, or, without any coexisting malaria, these phenomena may develop within a very few days. The frequent association of malaria with this form of the disease has done much to hang the whole beriberi symptom-complex on the malaria peg in the minds of those whose work has been confined to regions where both affections are rife.

The second group of the severe cases with slight cardiac involvement corresponds exactly to the picture conjured up by the words "multiple peripheral neuritis." If these patients are able to walk the diagnosis may be made at long range. If they are bedridden the most cursory examination will suffice. All the dear old text-book descriptions here come into their own: the "steppage" gait, the lost tendon reflexes, foot-drop, wrist-drop, atrophied muscles, areas of anesthesia, areas of hyperesthesia, areas of paresthesia—all the well-beloved phrases troop gallantly to service and describe with precision the unfortunate patient.

Mortality.—Of 797 patients admitted to the Candelaria Hospital during the years 1910 and 1911, 120 died—a mortality of 15.6 per cent. The mortality varies in a most extraordinary manner. Sometimes it will be not more than 2 or 3 per cent. for months, and then a time will come when half the patients die.

Pathology.—No one feature of the gross pathology as seen at our autopsies is characteristic. Atrophy of the skeletal muscles is sometimes present. In the acute cases it is absent. Dilatation of the right ventricle is almost invariably present. The left ventricle may be dilated. In old cases there is hypertrophy of the right ventricle. Pericardial effusion is fairly constant. The other serous cavities usually contain more or less fluid, and at times the whole cadaver is water logged. The kidneys may be congested, but there is no nephritis. The cardiac cases that have dragged on for some time may show chronic passive congestion of the liver.

Our attempts to estimate duodenal congestion have been unsatisfactory. The paraplegic cases seldom come to autopsy unless a terminal affection—notably bacillary dysentery—sets in. Signs of chronic malarial infection are, in this region, frequently present as a matter of course. No attempts to demonstrate degeneration of the peripheral nerves have been made.

EVIDENCE THAT THIS AFFECTION IS BERIBERI

In writing the foregoing I have sought to describe what I see here. I believe that I have presented a clinical entity which must be classified as beriberi. At any rate it constitutes my first proposition, namely, that this affection is beriberi. To the above one might add abundant historical evidence — if libraries occurred in the Brazilian forest. Leopold[3] referred to north Brazil as "the fatherland of the disease" [beriberi]. Bondurant[3] of Mobile, mentions Brazil first in his list of countries where beriberi prevails. Manson[4] speaks of the "epidemic wave" of the disease which passed over Brazil in the early sixties. Castellani and Chalmers[5] refer to Brazil as a place where beriberi is said to occur. Herzog[6] mentions the occurrence of beriberi on the Atlantic coast of South America and particularly in Brazil. Osler[7] has seen cases of beriberi from Brazil. Magalhães[8] wrote an exhaustive monograph on the cardiac phenomena of cases studied in Rio Janeiro.

RICE NOT A FACTOR

My second proposition is that this affection as it occurs in Brazil is not etiologically related to a diet of polished rice. To posit this negation requires some temerity on the part of a mere clinician, after reading the papers of Fraser and Stanton,[9] and many references to the work of Chamberlain and Vedder,[10] Heiser and others in the Philippines. I do it because I have seen some patients with beriberi whose diet was varied and abundant — who had not eaten a grain of rice for many months before the onset of the disease, a large number of patients with beriberi, who, enjoying a liberal, protein-abounding diet, had eaten it only occasionally throughout their lives, and a great number of sufferers from the disease, in whose diet it could not be considered the staple article. Of the latter class I have seen a goodly number who for months before the onset of the disease had had rice excluded from their diet.

Unlike the Oriental, the South American, by nativity or adoption is a meat-eater. He eats the European breakfast but he eats two full meals every day and partakes liberally of meat at both. Beans, which are supposed to have a therapeutic value in the treatment of beriberi in the East, are staple articles of diet throughout North Brazil. They abound on the tables of the poorer classes. *Feijoada,* a compound of bacon, red beans and dried beef, lightly touched with garlic and bathed in its own gravy is the dish universal among the poor, and not despised by the wealthy. The bean with meat is the staple article of food of the Brazilian peasant. Rice and *farinha* (cassava) and bananas are side dishes. It must be admitted that the Brazilian laborer eats some rice practically every day, and that the incidence of beriberi is perhaps highest in his class, but the same line of reasoning would incriminate polished rice as a causal factor in lobar pneumonia, malaria, uncinariasis and gonorrhea. Among our Brazilian employees lobar pneumonia is twenty times more frequent, relatively, than it is among our American employees.

In December, 1909, alarmed at the increase of beriberi among our employees of all classes, we caused rice to be eliminated from all company messes and removed from all the commissaries. In lieu of rice we furnished macaroni. The staple foodstuffs of the laborers were made to consist of dry biscuit, meat (dried and tinned meat and codfish), beans and macaroni instead of dry biscuit, meat, beans and rice. Conditions along the line of work were such that a large majority of the laborers were deprived of rice. The men who boarded at the company's messes ate no rice at all. The beriberi rate climbed steadily throughout the year 1910, and dropped abruptly at the end of the year exactly as it had done in 1909. In 1910 on a comparatively rice-free diet, there was relatively three times as much beriberi among our employees as there was in 1911, during which year all the messes and all the commissaries of the company served and sold rice freely. The rice has always been the same kind — white, polished rice.

[10] Chamberlain and Vedder: Philippine Jour. Sc., November, 1911.

One of our American physicians, who did not eat a grain of rice while in Brazil and who purposely refrained from eating it because of its supposed association with beriberi, contracted the disease after about ten months' service here and was invalided home Three other members of our staff, who lived at headquarters and who ate rice only occasionally, certainly not more than once a week, were invalided home with the diagnosis in both cases of beriberi One of these men ate at the table of the chief engineer, the other two lived at this hospital At neither table did rice appear except occasionally Two other physicians stationed in the camps contracted the disease and were invalided home Because one of these physicians had malarial parasites in his blood, when he got home, his affection was there diagnosed as "malarial neuritis" In all, six physicians have contracted the disease here — six healthy, young adults who lived on a full protein-rich diet

The incidence of the disease among physicians has been greater than among any other class except the Brazilian laborers Does not this fact alone speak volumes?

In 1910 out of a total of 690 admissions to the first-class ward of this hospital, there were twenty-four cases of beriberi Many of these patients came here and were invalided back to the United States during the time that rice was prohibited They did not eat a grain of rice They were clerks, mechanics, camp foremen, timekeepers, etc Their diet here would not have suffered, in comparison, as to quality, quantity and variety, with the diet of persons similarly employed anywhere in the United States Fresh meat, onions, potatoes and an abundant supply of the best American tinned meats, fruits and vegetables were supplied in lavish profusion, in addition to the bacon and beans which have belted the globe with steel rails Among the men from whom these cases were drawn (and no account is taken of a number of contract-expired men, who left of their own accord when the disease first manifested itself) the food-supply was above criticism from any standpoint

TIME INCIDENCE

If beriberi were due to polished rice, *per se,* one would expect its occurrence to be fairly uniform throughout the year, and from year to year, in a population that eats the same kind of rice in apparently the same quantities all the time Such is not the case Of 565 patients admitted to the Candelaria Hospital in 1910, 114 were admitted during the first six months, and 451 during the last six months of the year In 1910, 565 were admitted, in 1911, with a force of employees 25 per cent greater and the Brazilian contingent relatively much greater, 232 cases were admitted Practically, we, as well as the laity, recognize the period from July to December as being the beriberi season This was the case in 1908, 1909, 1910, and from present indications, it will be the case in 1912 The year 1911 was an exception, the admissions for beriberi being fairly evenly distributed over the twelve months

PLACE INCIDENCE

The constant shifting of laborers from camp to camp makes it well-nigh impossible to present figures of value as to relative admission rates for beriberi from the various camps That certain camps yield a much higher percentage of beriberi patients than others is, however, firmly impressed on the minds of all who have, in any capacity, managed the labor on this work In the fall of 1910 more than three-fourths of all the West Indian Negroes in one of our camps (Camp 16) contracted the disease The same camp furnished us beriberi patients of all nationalities, and of all grades of employment so long as it was active In the same year, of four West Indian Negroes living in a palm shack set back from the right of way in the woods, near Camp 22, two died of beriberi, a third was invalided to Manaos and the fourth with the "rudimentary" type of the disease was lost sight of No other cases of beriberi occurred in any of the other 200 or so laborers strung along the right of way for a distance of several kilometers The only thing in any way peculiar about this hut was that it was set back in the woods instead of being out in the open, as were the others In Porto Velho, in 1910, in a period of four months, of three men in succession employed as job printers in a certain house, two died of the disease and a third was invalided to Manaos In a period of five months in 1909-1910, three men employed as night watchmen in this hospital died of beriberi, and a fourth was invalided home with the same diagnosis A considerable number of our orderlies were attacked, one of our cooks, two of our nurses and, as stated, two of our hospital physicians

The rate has been very high among the crews of the company tugs that ply between Porto Velho and the mouth of the Madeira River In 1910, on two occasions, one of these tugs was put out of commission because of the death or disability from beriberi of her officers, especially her pilots and engineers The officers living "first-class" have had the disease at least as often, relatively, as the men The captain of one of the company's larger passenger carrying steamers was invalided home last year with beriberi The universal complaint of the first-class passengers on this steamer is that they get meat served in too many ways, with too much grease Fresh beef, dried beef, fish, potatoes, onions, bread made from American flour beans and rice, with tinned milk butter and fruits form the bill-of-fare on all these boats

I have seen cases of beriberi in robust people who have never had malaria or hookworms I have seen it in nearly all races and nationalities It has occurred here among all grades of employees It is, I think, more frequent among those whose resistance has been lowered by other diseases or by the abuse of alcohol Children usually escape and women are not attacked as often as men As most of our employees are young men, I cannot speak positively of the age incidence

CONCLUSIONS

1 A fatal form of peripheral neuritis occurs among residents of the Madeira Valley and among the employees of the Madeira-Mamoré Railway This neuritis must be classified as beriberi, or as a member of an as yet hypothetical beriberi group

2 This disease bears no intimate relation to the consumption of rice, polished or unpolished, as a staple article of diet

3 This disease is not due to the absence of protein in the diet of those whom it attacks

I desire to make acknowledgment to Dr E J Whitaker, whose assistance in the preparation of this paper has been most valuable

A FURTHER STUDY OF THE END-RESULTS OF THE CONSERVED OVARY *

JOHN OSBORN POLAK, M Sc, M.D
BROOKLYN

In 1909, I presented before this Section a report based on a study of the records of 300 cases occurring in my personal services, in which resection or conservation of an ovary had been done Since that time a large number of secondary operations have been necessary for the relief of symptoms caused by the retained or the resected ovary These explorations have given me a wider insight into the living pathology of the ovary or the part of the ovary which was retained in the effort at conservation

While I am still convinced that the importance of the ovary to the woman cannot be overestimated (not only is it the primary and all important organ in the reproductive cycle, but it regulates and controls the perfect attainment of development, growth and function in the individual woman, and its retention is essential to sex perpetuation), yet I must conclude from the study of the end-results of resection and conservation that frequently, owing to a defective appreciation of the living pathology of the ovary at the time of the primary operation and to our inability to estimate the effect which change of position and suture have on the retained ovarian structure, our attempts at conservation are often defeated

In this study I shall endeavor to differentiate between and draw conclusions from the end-results of the resected versus the conserved ovary It is surprising that so little clinical data of value have been contributed to the literature on resection and conservation during the past few years, for with the exception of the excellent analysis of the end-results collated by Clark and Norris, and the contributions of Peterson, Reynolds, Dickinson and myself, there is a dearth of new information On the other hand, much has been done in establishing the position and importance of the ovarian secretion Frank and Chipman have contributed excellent papers on this subject from which I shall take the privilege of quoting The parenchyma cells of the ovary secrete a substance or substances which react on the general body metabolism and control especially the nutrition, growth and activity of the uterus "This secretion is present at all times in greater or less quantity, but it is produced in greater abundance at recurrent periods, when it brings about those conditions of growth and hyperemia which characterize the proestrous or menstrual process After ovulation, which occurs during the estrous, the secretory cells of the ovary show still greater activity and cells of the ruptured graafian follicle become converted, largely by a process of simple hypertrophy, into luteal cells of the corpus luteum"

Chipman believes that the added secretion of these luteal cells an increment of quality of quantity, or of both raises the nutrition of the uterus which leads to those decidual changes in the uterine mucosa which insure the engrafting of a fertilized ovum When such engrafting occurs this secretion maintains the nutrition and growth of the placenta until the latter reaches its maturity The decadent and fibrotic changes which the placenta undergoes during the latter months of pregnancy are coincident with the retrogression and disappearance of the luteal cells

The ovary, while maintaining a perpetual secretion, undergoes a series of cyclical changes which increase or modify this ordinary secretion, and with these, the changes in the uterus are correlated While the exact nature of this secretion is not known, it is definite that the loss of the ovary means the loss of sex influence to the individual, and produces grave disturbance in the general metabolism The earlier in life the loss of the ovarian secretion occurs, the greater is the calamity, though clinical observation shows that the severity of the nervous phenomena differs in different individuals, as, for instance, the nervous symptoms are less subsequent to operation and the general health of the woman better when a hysterectomy and double oophorectomy have been performed for suppurative conditions in the pelvis than when a total ablation has been made for fibromyomas Again, it must be admitted that an ovary conserved for the ovarian secretion, if unhealthy, will leave the patient in a worse state mentally, nervously and physically than if total extirpation had been made

In regard to the types of ovary which can be conserved, my experience is in accord with that of Reynolds, that a moderately enlarged ovary, the seat of multiple follicular disease, may be reduced to the normal size, placed in a proper position in the pelvis, and retained with considerable hope that the dysmenorrhea and catamenial depression will be greatly improved, also that an ovary that has been in bad company may be dug out of a capsule of adhesion, the original focus of infection having been removed, and may go through such reparative changes as to become a useful organ An enlarged ovary is not necessarily a diseased one, for the size of the ovary is affected by its position A continuance in a bad position leads to changes in its tunic which favor the production of follicular change and retention-cyst formation

The natural and proper conservation of the ovary consists in leaving it alone, and in placing it in such a position in the pelvis without twisting the ovarian ligament that there is no obstruction to its afferent or efferent circulation An ovary should never be conserved and then allowed to drop back into the pelvis in a dependent position When there is interference with the efferent circulation, changes in the ovarian structure rapidly follow the organ swells from passive congestion, the stroma increases, the tunica thickens developing follicles become imprisoned, the amount of intrafollicular fluid is rapidly increased and retention-cysts form, often growing with great speed I have already reported a case of cyst formation within six days of the primary operation, due to a twist in the utero-ovarian ligament which interfered with the efferent circulation

The distinction between conservation and resection is not properly understood by the profession Excision of a portion of diseased ovary is conservative but not conservation, and the prognosis as to the final outcome of the conserved versus the resected ovary differs widely Conservation implies that the ovary is relatively normal, while resection deals with an organ more or less diseased

The ovary which can be resected with a fair degree of success is the ovary with a large monocyst on its surface, the small dermoid, or the fibroid, from which we are able by careful dissection to retain a sufficient quantity of healthy ovarian structure to make a functionating ovary It has been proved that the ovarian ligament which hypertrophies as a consequence of cystic changes frequently contains active parenchyma tissue, and that the ovary possesses a considerable capacity for regenera-

* Read in the Section on Obstetrics and Gynecology of the American Medical Association at its Sixty Third Annual Session held at Atlantic City June 1912

tion of tissue after its partial removal, if its circulation is not interfered with.

The influence of position on the conserved or resected ovary is a subject which has not had sufficient consideration from operators. My own experience has taught me that when anything interferes with the efferent circulation of the retained portion of ovarian tissue or the conserved ovary whether it be the position in which the ovary lies, as when it is dependent on the misplacement of the ovarian suture, or because of a misplacement of the uterus, which carries the ovary down with it, or when a salpingectomy has been made without due regard to the utero-ovarian anastomosis, the ovary becomes heavier and tends to fall into the culdesac and to change in its size rapidly.

As the surgeon becomes better acquainted with ovarian pathology and the necessity of the ovary being in proper position, fewer and fewer ovaries are removed. Our early mistake was not to recognize that multiple cystic ovaries were the result of interference with the efferent circulation and thickening of the tunic, both of which were due to the dependency of the organ occasioned by hyperplasia, etc. There is probably no part of surgery in which long experience and study of the living pathology is so important as in the decision of what shall be done with a particular ovary which is enlarged to two or three times its normal size.

To ascertain the end-results of the conserved versus the resected ovary, I have selected and tabulated from the records of my clinic since May 1, 1909, 229 cases in which some conservative procedure on the ovary has been practiced. There has been no primary mortality.

In sixty of the women operated on it was possible to retain both ovaries after freeing them from the associated adhesion produced by their infected or diseased neighbors, the uterus and tubes. In each of 102 cases, one ovary was conserved while extensive resection was done in but sixty-seven cases. No attempt was made to save pus ovaries. Enlarged, adherent, edematous, prolapsed and multiple cystic ovaries of moderate size were retained and tacked up in proper position in the pelvis without any attempt being made to diminish their bulk, except by the puncture of small cyst formations on their surface. The results have on the whole been gratifying, for out of twenty-four secondary operations in this series only three necessitated the extirpation of the conserved ovary, as against twenty-one ablations of the previously resected ovary.

I have been able to follow and keep accurate records of 181 patients out of the 229 operated on, and over 150 have been examined at monthly intervals, for periods varying from three years to two months, thus allowing us to make accurate notes and drawings of the exact pelvic conditions.

In this series there were twenty-eight resections of the ovarian structure from large monolocular cysts whose cavities contained from 1 to 10 pints of fluid, in which it was practicable to save sufficient ovarian tissue to construct a serviceable ovary about 2 by 5 cm. in size. Observation has shown that such an ovary during the first four weeks following operation undergoes a primary enlargement, sometimes attaining a size two or three times that of the portion conserved. It then slowly begins to shrink, to lose its tenderness and to perform its functions naturally. At the end of three months, on physical examination, the involution seems complete. None of these women have returned for reoperation. Two are now pregnant, and all have menstruated regularly since the operation. In three instances the type of the period is changed in time and duration and the quantity of blood lost each month has gradually diminished. None has shown any of the nervous phenomena of the menopause. Twenty-one have been examined in the past three months and their records show that seventeen have pelves free from exudate. The ovary is of normal size, in high position, palpable and not tender. Painless enlargement was present in the remaining four. All are at present enjoying good health.

An analysis of the twenty-four cases of this series coming to secondary operation, in which we were able to study the living pathology of the conserved or resected ovary in the pelvis and after its removal, has given us some helpful hints as to what to do next time.

The abdominal findings have been more or less consistent. The conserved or resected ovary has presented further cystic changes which have involved the entire structure and have always been attended by a low type of peritoneal inflammation, producing thin, diffuse adhesions most difficult to handle. This condition was noted in eighteen cases in which the left ovary had been retained, while only six women who had had the right conserved or resected have come to a secondary exploration. Thin-walled cysts of the size of an orange had formed on the resected ovary in four patients. In these the adhesions were particularly dense and extensive. It was evident that the sigmoid and omentum had promptly become attached to the suture line. A gradually developing amenorrhea or a persistent metrorrhagia was present in all of these cases.

These observations have suggested the following conclusions:

1. Only healthy ovaries should be conserved.
2. The right ovary when retained is less prone to subsequent inflammatory changes than the left.
3. All retained ovaries or portions of ovaries should be placed in such a position in the pelvis that their circulation is uninterfered with.
4. Resection gives the best results when its application is limited to large monocysts, retention-cysts, fibroids or dermoids.
5. The multiple cystic ovary should either be left alone or ablated. Resection is not permissible.
6. When a resection is made it should be extensive, excising the entire diseased area. The suture should only approximate the wound edges, not constrict them. The retained portion should be tacked up in the pelvis to maintain an equal circulation, and the suture line should be always covered with a reflexion of the peritoneum.

287 Clinton Avenue.

ABSTRACT OF DISCUSSION

Dr. Le Roy Broun, New York: In deciding during an operation what course should be pursued, I am largely influenced by the age of the patient, the primary thought being, however, to have the pelvis in such a condition that secondary operations will not be invited by subsequent pathologic changes. I have had no experience in resecting ovaries other than in a few instances when, on account of the youth of the patient, it was imperative that as much as possible of the secretive surface of the gland should be preserved. These were instances in which a corpus luteum cyst had become pathologic in size. On the whole, it has never been my custom to meddle with ovaries with small multiple cystic follicles. For such conditions are evidence of disturbed circulation in the ovarian tissue and should be treated not by resection and leaving the ovary in the same position as before, but by lifting and retaining the ovary in a plane more nearly approaching the normal.

In the presence of adhesions, better results are obtained by using a sharp dissector rather than the fingers.

Where it is necessary to remove a tube, I hesitate greatly to leave the ovary, and rarely do so when the other ovary is unquestionable, except at the request of the patient, or in instances of young women. When the woman is at or near the menopause, or when the other ovary and tube are healthy, I believe it is to the interests of the patient to remove the ovary, together with the affected tube My reason for this belief is that no matter what method we may use for anchoring the conserved ovary after its accompanying tube has been removed, the disturbance in the venous return will, at times, be sufficient to set up pathologic changes in the conserved ovary sufficient to necessitate a second operation, which will at all times be more serious than the original operative procedure on account of the adhesions developing in the wake of the circulatory disturbance

In such conditions the after health of the patient is far better when the ovaries are removed at the same time than when we conserve them in whole or in part In instances of such conservation there has been, as a rule, a long period of tender ovaries, treatment and mental unrest In instances of hysterectomy for fibroids, the nervous disturbance of the menopause is lessened when the ovaries and tubes can be conserved, and I believe in general it is of advantage to the patient to do this In these instances, however, I have been forced to operate a second time on four patients for developed cysts in one of the retained ovaries My practice is at present to conserve the ovaries and tubes in such instances if possible when the patient is young, but to remove them when the patient is at or near the menopause

Dr W B Dorsett, St Louis I have had some very startling experiences following resections of the ovary in cases of dysmenorrhea, the conditions being entirely relieved by resection I do not mean to say that all conditions of dysmenorrhea can be relieved by resection of the ovary There is much in the technic that should be closely observed The resection should imply that a portion of the ovary is removed, not simply the opening of a cyst with the needle and dissecting it out In some cases it is almost impossible to scrape out the cyst and therefore a large portion of the ovary should be removed In doing so a wedge shaped piece should be cut down to the very edge of the ovary so that all cysts can be removed by the two incisions Regarding the covering over by the peritoneum mentioned by Dr Polak, there are two classes of ovaries that give me trouble those with very thick and those with very thin coverings In both there is tearing out when the needle is put in It is necessary to carry the needle down to the very bottom of the deepest portion in which the ovary has been incised that is when the wedge shaped piece is removed I agree with Dr Polak on the advantage of anchoring the ovary after operation One half of the results obtained are due to the suspension of the ovary rather than to the resection

Dr H. J Boldt New York In my experience the ordinary cystic degenerations of the ovary are absolutely different They gave no symptoms and were left alone Taking out a wedge shaped piece seemed useless In a large ovary it may be done, not for the purpose of removing part of the ovarian structure but for the purpose of decreasing the size of the ovary or of diminishing its weight It is possible that we may at times be compelled to do a secondary operation because of a cyst forming in that ovary Yet it is not desirable invariably to remove ovaries that seem to be healthy I should always retain the ovary, no matter what the condition causing the abdominal section so long as it was macroscopically in good condition Particularly is this the case in ovarian tumors With apparently no more functionating stroma, I have been able by shelling out the tumor to retain the ovary In one case in which it was necessary to remove the complete ovarian tissue on one side the other ovary had joined in the tumor It would have been most disastrous for the future of that patient to have taken out the ovary I was able to preserve sufficient of the ovarian stroma to continue to functionate, the patient is now married, and I have no doubt but that a satisfactory result will ensue Therefore, whenever an ovary is sufficiently healthy to retain its function I retain it

Dr. F J Taussig, St Louis My experience is based on three secondary operations but they have all been done on ovaries a portion of which had been left on the left side, and I have found that the cyst wall was always closely adherent between the ovary and the sigmoid or rectum The question arises, What is the cause of this increased frequency on the left side? When the two ovaries are equally good and there is no material reason for choosing one in preference to the other, of course, we would as a result of this evidence prefer leaving the right ovary and removing the left entirely But when the right ovary has to be removed and we are compelled therefore, in order to have any ovarian tissue left, to utilize the left ovary, we ought to see how we can vary our technic to diminish the number of cystic conditions following It occurs to me that the closeness of the intestine may be the main feature in this matter, and that if we draw the intestine over toward the right side by a suture, it might reduce the frequency of cyst formation

Dr T J Watkins, Chicago I agree with Dr Polak on the indications for the work His method of covering the line of sutures with the peritoneum would seem to me to be original with him, and I should like to ask if he has been doing that for a long time There is a possible danger of the development of follicular cysts from not leaving the ovary free. It has the advantage, however, of covering over the raw surface. I have been going a little further than Dr Polak. I have occasionally resected small abscesses in the ovaries in young women, preferring to run the risk of secondary trouble to producing an early menopause As yet I have had no unfavorable results so far as we know We have operated a second time in some ovaries of much the same class as mentioned by Dr Polak, cases of perioöphoritis in which the ovaries became cystic after operation In resecting these ovaries, the greatest danger has appeared to be from the formation of adhesions Lately if both ovaries have been affected, I have resected only one In resecting ovaries of late I have left less tissue, leaving only a comparatively small part of the ovary that is attached at the hilum, but in none of these cases has the menopause been produced What should be done in cases of so called sclerocystic ovaries is still a problem The pathologist has not yet determined whether they are really pathologic We have no idea what produces them and we have very little observation as to what becomes of them when they are left We should keep such patients who have not been operated on under observation for the purpose of determining what really becomes of these so called sclerocystic ovaries

Dr H. P Newman, San Diego, Cal I would have supposed that the removal of ovaries for menstrual pain—"ovarian dysmenorrhea," so called—and neurasthenic conditions in general, was no longer a debatable question in an organization like this Ovarian surgery has passed the experimental stage and no longer justifies the removal of the organs in young women for disturbed function, pain and nervous symptoms In view of the deplorable situation in which a woman in early menstrual life is placed on the sudden and complete cessation of this function, we are reluctant to do the necessary radical work even in cases of malignancy, uncontrollable hemorrhage and those pathologic conditions for which there is as yet no other relief And as for cystic and sclerotic conditions we no longer extirpate for them About the hilum sufficient ovarian structure for healthy functioning will be found, and by plastic work we may excise the degenerated tissue and retain enough normal to insure ovulation as well as menstruation, so essential to the well being of the young woman We may look perhaps, in the direction indicated by the reports of the newest developments in organotherapy and ovarian transplantation for suggestions of relief for those unfortunates who are now paying the price of radical operations, necessary or not formerly done, in whom there is no possibility of return to normal and who appeal to us for assistance in the effort of the nervous system toward compensation

Dr W B Dorsett, St Louis I hope Dr Newman did not understand my position to be that of removing ovaries for dysmenorrhea I said I had had remarkable results in the treatment of dysmenorrhea by resecting the ovary I did not report, and do not know that anybody has reported, removal of the ovary for the treatment of dysmenorrhea.

Dr. J O Polak, Brooklyn Dr Taussig in speaking of my method of resection implied that his conception was that there was no peritoneum to the ovary I do not cover my wound in the ovary with the peritoneum of the ovary I try to use the back of the broad ligament so that I turn the scar into the broad ligament It came to my notice a year and a half ago in reoperating on a woman in whom I had done a resection She came back to me because of adhesion of the sigmoid to the suture line of the right ovary which was down in the culdesac I separated that adhesion and made a further resection as it was the only ovary the patient had and she was young I partially turned the ovary on itself burying the suture line in the broad ligament, with satisfactory result I have continued that procedure The one point which I do wish to bring out is that true conservation is leaving the ovary alone, and that the best result I have had in resection has been in the resection of large ovarian cysts in which apparently there is no ovarian structure, and yet in which by careful resection it has been possible to retain a functionating and menstruating woman Two of the patients so treated are now pregnant This is a small percentage of the whole number of cases but is sufficient to show that the ovary even after marked resection is capable of producing an ovum

HEREDITY IN NERVOUS DISEASE AND ITS SOCIAL BEARINGS*

C B DAVENPORT, M D
COLD SPRING HARBOR, N Y

My theme is old, yet every topic into which heredity enters can now, in view of the recent advances in this study, be viewed in a new light So possibly I may be able to present ideas in a new way

Mental abnormality may be divided into two sorts lack of development and weakness Let us consider the origin of each sort The development of an individual is a complex of processes which work individually to the production of specific organs, and collectively to the development of the individual as a whole Modern studies in heredity indicate that, typically, each part develops to a certain extent independently of every other, at least in the early stages Later the secretions of thyroid and thymus, testis and ovary, and doubtless other organs, exert a general or a specific influence on development Finally, insufficient nutrition of the embryo or the presence of certain poisons may exert a wide-spread inhibiting effect on developmental processes Even starvation exerts a somewhat selective influence since all organs are not equally retarded, and there is reason for concluding that malnutrition and poisons have a different effect on different persons, retarding those in whom the internal impulses to development are weakest Consequently, it is difficult to draw inferences as to the influence of alcohol on the development of man from its influence on the development of guinea-pigs It is stated that when guinea-pigs and rabbits are subjected to alcohol their young develop imperfectly There are many detailed family histories in which both parents have been alcoholic sots during the reproductive period, and yet they have produced children without spina bifida, harelip, cyclopia or other marked teratologic conditions

Failure of mental development may, on the classification adopted, be regarded as of four sorts

1 Intrinsic and general, producing idiots and cretins
2 Intrinsic and specific, producing the feeble-minded
3 Extrinsic and general, resulting (it is alleged) in abortions, miscarriages, etc
4 Extrinsic and specific, causing (perhaps) some cases of harelip, eunuchoidism and some other defects

Of the four classes, the second is the commonest From my point of view feeble-mindedness is the failure of development of specific mental traits, the determiners for which are not present in and have never been acquired by the germ-plasm The defects are a direct inheritance from our remote ape-like ancestors in which the trait had not yet been acquired The feeble-minded have gained most human traits, but not all the mental ones

The group of the mentally weak includes those persons who, under the influence of stress, break down mentally The stress reveals the hidden weakness but does not cause it Studies of the families of epileptics, dementia praecoxes and manic-depressives reveal the fact that they belong to strains with mental weakness If we inquire whence these strains arose, no final answer can be given, but the suggestion may be made Every person has a weakest part, we are not like the "one-hoss shay" And there is evidence that there are human strains that are not resistant to attacks on the respiratory tract, others whose weakness is in the circulatory system, others whose alimentary tract is the first to give way, and others whose nervous mechanism cannot stand great stress And those persons who go insane belong, for the most part, to this last set

The origin of these insane families may well go back to their animal ancestors, for animals are characterized by precisely these same strains Or we may say that the mentally weak include those mental adjustments which have not kept pace with the increasing demands of our civilization Neural weakness in man is probably a direct transmission from neural weakness in lower animals

From this point of view, the origin of a feeble-minded child, which seems so like the visitation of an offended God, is merely the necessary cropping out of inherited animal traits, and the origin of a functionally insane person is, within limits, determined by a fortuitous combination of weak determiners

Leaving for a moment the matter of the origin of neuropathic strains, let us consider their relation to society Society is an organization of a gregarious species for development of common interests through cooperation and division of labor Social progress implies mutual understanding, ability to cooperate and to play one's part well, while regarding the good of others Society is built on human behavior, and the behavior of an individual at any time is his reaction to the stimuli that fall on him The reaction is determined not only by the stimulus but also by the individual's make-up, both that part which comes through heredity, and that which comes through training (which, in turn, is largely influenced by heredity) Society has decided that certain kinds of behavior — reactions — are, on the whole, good for the development of society, and that certain others are bad The inability to learn to count, to read, to write, to distinguish colors, the lack of ambition, of foresight, of industry, of inhibition to drink, of sex control and control over other emotions, such as anger, fear, hatred, suspicion and revenge, the strong desire to take the property of others, to realize excitement by conflagrations or by false tales the tendency to seclusiveness, to shyness, to conceit, to periods of depression, to hyperexcitation and exaltation, to expansive ideas, to loss of memory, to loss of orientation, to cruel treatment of animals and children — all of these reactions are "inheritable" and are bad for society, which has labeled them "bad behavior" The persons who behave this way are incompatible with a safe and progressive social organization, and they should, in the worst cases, be segregated to protect society, and above *all that they may not reproduce their kind*

---

* Read in the Section on Nervous and Mental Diseases of the American Medical Association at the Sixty Third Annual Session held at Atlantic City June 1912

Society's method of dealing with those who exhibit antisocial behavior is often inadequate The theory of treatment is (1) to avenge the misdemeanor, (2) to give pain, so as to supply a deterrent to the individual, and (3) to set an example of consequences which shall act as a deterrent to others

The first motive is clearly illogical, as the persons who act antisocially cannot properly be held responsible in this behavior in the sense of deserving pain The occurrence of recidivists who form a large part of all "criminals" indicates the inadequacy of the second aim As for the third aim if the punishment of the individual is of little effect on him, it is clear that it must be of much less effect on another As a matter of fact, there is little evidence that punishment has any effect except in minor antisocial behavior Since punishment is inadequate in the case of the grosser breaches of conduct the whole system should be abandoned and replaced by lifelong restraint like that afforded the imbecile and permanently insane

Finally, since most if not all kinds of nervous disease have the hereditary element, it is clearly desirable that such disease should not be perpetuated by unfit matings such as between two strains containing nervous weakness In order that such marriages may not occur, the fact of neural weakness in a family strain should be known to one contemplating marriage into that strain It is the duty of a physician in the exercise of his broad function as eugenist, to warn young people who are contemplating a choice that is clearly unfit The rule of secrecy in family affairs enjoined on physicians should not apply to prevent a physician from speaking in such cases even as the laws in some states are requiring him to report venereal disease Any rule of secrecy which acts against the progress of society, and especially against fitness for marriage is a grossly antisocial, immoral law, and should be repealed Not infrequently the student of the heredity of a characteristic has to ask the physician concerning the occurrence of a characteristic in a given person A B, whom the student knows only as the name appears in some pedigree with which he is working occasionally the physician, usually a young man, declines to assist on the ground that he is not at liberty to give the desired information Knowledge that might well lead to conclusions of great import to humanity is withheld in the blind following of a rule whose main motive is praiseworthy but whose application is too broad *Inheritable traits are not personal property* They come to the individual from down the ages out of the society of the past, they will be disseminated if the person or his fraternity have children, into the society of the future What right has the momentary possessor of the trait to claim it as his private and personal affair? A knowledge of his traits belongs to society is it not wrong for the medical profession to maintain these false ideals of the private nature of inheritable traits?

If the defense is that physicians must protect those by whom they are paid even at the expense of society, then the sooner the state takes over the whole matter of private as well as public sanitation the better A relation that was satisfactory when disease was regarded as a personal and private matter is inadequate now that health and disease are properly regarded as public and social affairs I do not see any logical outcome of the development of medical science but this that the health of the individual shall be regarded as one of the principal interests of the state, and that eugenics, as determining *liability for disease or for imperfect* development, shall be recognized as one of the principal divisions of state sanitation

---

ABSTRACT OF DISCUSSION

Dr L Pierce Clark, New York Many, if not most neurologists, make a special point of advising their patients regarding the matters laid down in Dr Davenport's paper The whole subject will take an immense jump forward in practical impetus when we can predict the future outcome of different kinds of matings The matter is now largely a case of spilled milk or locking the barn after the horse is stolen To control and manage all medicine is a questionable procedure for any class of society, certainly an extra hazardous venture as our society is constituted to day The crying need of the moment regarding sterilization is more definite information and not more legislation The latter is now far outrunning the former In Connecticut they have not made use of their anti marriage law of the unfit at all as the people are not back of it I understand that a reactionary tendency is in progress in Indiana also The main practical issue to day is to collect and study facts regarding sterilization of the unfit teach the people the importance of application of these facts and follow a well thought out plan of legislation After all the prophylaxis of preventing marriage of the unfit, rather than sterilization, will be the truly rational approach to the problem

Dr A C Brush, Brooklyn We must consider this question seriously before we push any measures to the point of *legislative enactment To start a public campaign on the* matter of the new series of transmission of hereditary tendencies too abruptly would be unwise According to one pronouncement of the mendelian law, if a man with psychopathic tendencies marries a healthy woman and four children are born, two will be psychopathic and two normal Without knowing whether or not a young person will develop psychopathic tendencies have we a right to interfere with the marriage, or how will we select those with psychopathic tendencies? I wish Dr Davenport would consider that in summing up I am not, however, advocating the theory of striking at the whole family, that would be an injustice.

Dr Woods Hutchinson, New York The public mind is becoming quite receptive to these ideas, even though at first sight as repulsive as that of sterilization The strongest expressions of objection to the new legislation and doubts cast on the wisdom of it come from the medical profession rather than the laity As Dr Davenport says, the more carefully these defectives are studied, the more the hereditary element comes out in them At the training school at Vineland, N J, they have clearly demonstrated that from the union of a feeble minded man and a feeble minded woman never yet was born a normal child, and in the various matings between sound and feeble minded persons the defects appear in offspring almost in mendelian proportions In investigating criminals born in Indiana I have shown that nearly 50 per cent of them are traceable to 150 families The problem is one of great importance, and its solution is feasible and practical It involves the sterilization of only about 3 per cent of the community, and within two generations we should have at least diminished by three quarters our criminals, prostitutes, insane, epileptics feeble minded and inebriates I spent a week in a reformatory where sterilization has been carried out to the fullest degree, out of 700 sterilizations on confirmed criminals, over 600 were at the request of the men involved They are willing to protect themselves and society against this possibility, if society will approach them in a kindly, broad, liberal and sympathetic spirit If we could make our influence felt in the courts and study the individual history of these criminals, we could accomplish something I asked a famous detective if he knew anything of the history of the McNamara brothers, the dynamiters The general statement had been made that these men were ordinary members of society who had gradually let the lust of blood and hatred of capital grow on them until they committed crime "Yes," he said, "their father was in jail twice, once for assault for attempted murder, and once for incest with his own feeble minded child, sister of the two criminals, and there was another feeble minded child in the family" And yet that matter was threshed out for months in the press and the courts without any question as to the mental responsibility of those two men I believe that what we as physicians have to say on this subject, based on a rational, broad, humane regard for the unfortunate, should have weight. Of course, we know that 60 to 75 per cent of the fallen women are definitely mentally defective We should look on those people as our unfortunate brothers and sisters who fail to develop, who need our care, sympathy and protection and not our hatred and punishment Then, if we rise to our possibilities, we shall reform society, wipe out crime and reform even our courts and the legal profession

Dr William W Graves, St Louis I would call attention to the fact that in clinical medicine some attention is invariably paid to that part of the study called family history, but up to the present, so far as I know, the data thus derived have been based largely on hearsay testimony Family pride and foregetfulness and, in some, untruthfulness render the data thus secured inaccurate As much as I would applaud the good accomplished by field workers in the collection of data bearing on family histories, yet the study of the individuals of families in a comparative clinical way will yield just as important and even more definite information bearing on those factors which make for a bad heredity In our studies of the problems of heredity it is not sufficient to depend on hearsay testimony, we must apply, in addition, comparative clinical methods to these problems We know of no standard of humanity except that which is established by the parents It is obviously unfair to compare the members of one family with those of another because the determiners of the ascendents represented in the parents are different in each family If we will utilize in our studies of heredity that standard which is established by each pair of parents and study the parents and the progeny in a comparative clinical way, we shall get back to first principles It is recognized everywhere that well mated and healthy parents, as a rule, produce healthy progeny, which compare favorably one with the other and each in turn with the parents, so that, utilizing the parents as standards and approaching the problems of heredity in a comparative clinical way, in addition to estimating hearsay testimony at its full worth, we shall not only be able to determine the effects of bad mating but also to determine those factors of disease which make for bad heredity

I was pleased to hear Dr Davenport say that recent studies have shown that alcohol has not played that important rôle in the production of bad heredity which we have heretofore believed it did My observations are wholly in accord with this view There is a disease, however, which has as yet failed to receive full consideration as a cause of bad heredity While we have recognized that syphilis may be transmitted to the offspring, we have recognized as "tainted" only those who show Hutchinson's teeth, interstitial keratitis, deafness without otitis, bone, joint, skin and mucous membrane affections, the other progeny of syphilitic parents who have not shown these signs we have considered as healthy individuals Comparative clinical studies of the progeny of syphilitics will show how false are our present conceptions in regard to the effects of this disease Such studies generally applied and using the parents as standards will not only enable us to determine the effects of good and bad mating, but will also enable us to determine the diseases which render a good heredity bad and a bad heredity worse

Dr E E Southard, Cambridge, Mass Whatever may be said against the field workers and their lack of intimate medical knowledge or anthropologic knowledge, which are not really always necessary, there seems as yet to be no instance of a normal child born from feeble minded parents The same cannot be said, I think, of insane parentage, but there are few data in this direction We are apt to synthesize the conditions of degeneracy, insanity, epilepsy, inebriety and the like, including crime and pauperism, under the same category, without due attention to the different parts which hereditary and non hereditary factors play Take Dr Brush's problem concerning the marriage of a normal person with a degenerate Suppose the degenerate to be a feeble minded person, there would be strong doubt in my mind whether the man desirous of marrying her is normal I think that problem is not so common as it is in mendelian fields, where we can control the sexual relations The marriage of two insane persons, I think, is relatively infrequent At least I endeavored to collect data in this direction in the state of Massachusetts, which is supposed to be a highly degenerate state I found a few instances of the union of two persons degenerate in the direction of insanity The problem of the union of epileptics is economically a smaller one, it is not likely that two epileptics would marry unless they were also imbecile I remember one meeting in which a man stated that he had a very good example of heredity A grandfather, a father and a son showed epilepsy "This," said he, "would form a good example for the hereditarian" But it turned out that the grandfather had senile arteriosclerosis with late epilepsy The father was syphilitic, and the son had polioencephalitis with ensuing epilepsy It seems hard for medical men to understand that most series of facts are a result of a conspiracy of factors, and in this conspiracy the hereditary and the non hereditary factors may both play an important part Which is the more important is the question Medical men call certain conditions hereditary. What are the factors in these cases? The factors are mandatory The children are under certain mathematical rules, subject to the disease of the parents But there are conditions in which the hereditary factor is not mandatory, it is what the lawyers call permissive, and if the other factor that sets off the disease does not come into the life of the offspring, then the disease stands out and the heredity is so far concealed. On this line of distinction between the mandatory and the permissive types of factors in inheritance, I think that one may tend to resolve the difficulties which arise, when hereditarians on the one hand and the medical etiologists on the other get together and cannot come to terms

Dr Tom A. Williams, Washington, D C I was surprised to hear Dr Davenport say that many of the traits which prevent a proper adaptation come from the lower animals Of course, all our traits do originally come from the lower animals But why select those particularly as coming from the lower animals? We should not refer to our remote origin in animals for such traits, but to the fact that there has been the acquisition of an unsuitable character in the germ plasm—not an acquired character, but a modification of the germ plasm through some noxious influence It is not conceivable that a feeble minded race can have survived through the eons of time through which the human species has persisted

Those who should not marry and should not transmit are those who are the possessors of undesirable traits If when an apparently desirable person happens to transmit to his or her offspring undesirable traits, such undesirable offspring should be prevented in their turn from begetting or bearing children, even though he may produce some healthy progeny

There are certain tendencies which develop in children as well as in adults which are not the propensities of the race at all, but which occur by reason of the extreme differentiation of the reactions in different parts of the brain due to environment and other causes, which make it easy to pervert the natural tendencies, the capacity for which is inherent considering the great complexity of the cortical substance in man it is very easy to pervert tendencies entirely by environment or education One of the instances used by Dr Davenport was pyromania, another, excessive libido Each of these particular characteristics in an adult may be induced in childhood by a series of circumst ade those particular practices to him there
individuals in whom the d ous,

Lackey, Canton, who was a member of the legislature which passed the act granting $30,000 to the State Board of Health and to whom credit is given by the secretary of the State Board for its passage Dr Homer Blane, Cadiz, the president of the society, acted as toastmaster and many communications from friends of Dr Lackey were read. Dr J W Crenshaw responded to the toast, "Dr Lackey, as the Public Do Not Know Him," in which he paid eloquent tribute to the noble work of the beloved country doctor and expressed the regret of his colleagues at Dr Lackey's change of residence to Nashville Dr Lackey made a suitable response

LOUISIANA

Leper in Winnfield—A Mexican, who has been in Winnfield for a month or two, has been discovered to be a leper, and has been sent to New Orleans to be treated there or placed in the lepers' home

The Hebert Case—The sheriff of Lafayette Parish has arranged to place a guard over the home of Hebert the insane leper at Lafayette, who recently escaped from the State Leper's Home

Isolation Ward Needed.—Dr Joseph A Dana, house surgeon of the Charity Hospital, New Orleans, strongly recommends the erection of an isolation hospital for the treatment of contagious and infectious diseases

Sanatorium Opened.—Crowley Sanitarium, which has been in course of construction for several months, is practically completed and will soon be opened The officers of the institution are Dr E M. Ellis, president, Dr D D Mims, vice president, and Dr R B Raney, secretary treasurer

Tuberculosis Cottage Dedicated—New Orleans Typographical Union No 17 dedicated a cottage at Camp Hygeia, the colony of the New Orleans Antituberculosis League in St Tammany Parish, October 27 The cottage has two rooms, has been completely furnished and screened and is ready for occupancy

The State Board's Thanksgiving—Dr Oscar Dowling, president of the State Board of Health, promulgates the following as the Thanksgiving proclamation of the board

> For the constantly increasing public interest in subjects akin to sanitation and preventive medicine for the loyal support as a whole of the medical profession of the state for the almost unanimous cooperation of the public health officials national and local and last but not least for the good will of the united press the Louisiana State Board of Health offers its most sincere thanks

Personal.—Dr E M Hummel, New Orleans, suffered a fractured rib and lacerations of the scalp in a collision between his automobile and a trolley car, December 1——Dr W T O'Reilly New Orleans, has been made superintendent of public health——Dr Chaille Jameson, head of the laboratory demonstration work of the New Orleans Tropical School of Medicine, has returned from Port Limon, Costa Rica, where he installed a laboratory for the United Fruit Company——Dr Oscar Dowling has been reappointed president and a member of the State Board of Health to succeed himself——Dr G C McKinney, Doyle, has been appointed a member of the State Hookworm Commission——Dr J D Fulton has succeeded Dr J W K. Shaw as city health officer of New Iberia and coroner of Iberia Parish——Dr Charles V Unsworth, New Orleans, has been appointed physician in charge of the Louisiana Retreat, vice Dr St Mark Fortier, deceased

MARYLAND

Public Health Lectures—Dr William W Hobson, on behalf of the Medical and Chirurgical Faculty of Maryland, is making arrangements throughout the Eastern Shore for a series of public health lectures

Baltimore

New Officers—Baltimore City Medical Association, December 3 president, Dr Harry Friedenwald, secretary, Dr Emil Novak

Nurses' Home Opened.—The Hecht Memorial Nurses' Home at the Hebrew Hospital was opened December 1 The building is three stories and a basement in height and has accommodation for sixty nurses

Increased Appropriation for Health Department.—The Board of Estimates has made an appropriation for the health department for the coming year amounting to $218,415, an increase of $15,310 over the appropriation for 1912

Small-Pox.—During the recent outbreak of small pox there were five cases which were sent to quarantine Vaccination was done very generally in the affected section and thirteen who had been subjected to the disease were isolated The disease was said to have been brought to Baltimore by a negro from Cumberland, and all of the patients are negroes

Personal—Dr L McLane Tiffany was operated on at the Union Protestant Hospital, December 2——Dr Thomas R Brown, who has just returned from Europe, has been placed in charge of the clinic on digestive diseases at the Johns Hopkins Hospital——Dr Lloyd P Shippen inherits $1,000 under the will of the late Dr Richard A Cleeman, Philadelphia

MASSACHUSETTS

Reorganization of Staff—The department of general surgery in the Boston Dispensary has been reorganized and placed under the charge of Drs Benjamin Tenney and John Homans, each to be on duty for six months Dr Frederick M Briggs has been appointed consulting surgeon and Drs Robert H Vose, Theodore C Beebe, Henry M Chase and Henry D Lloyd have been made assistant surgeons in charge of the genito urinary department

Personal.—Dr Charles F Whitney, Boston, has been appointed assistant professor of physiological chemistry in the University of Vermont, Burlington, vice Dr C F Dalton, who has been appointed secretary of the State Board of Health——Drs William E Synan and J N Landry have been elected members of the school committee of Fall River——Dr John F Croston has been elected a member of the school committee of Haverhill——Dr O W Roberts has been elected first vice president and Dr A C Eastman a director of the Springfield Baby Feeding Association.——Dr W J Collins has been elected chairman and Dr J E Hayes a member of the executive committee of the Northampton Antituberculosis Society

MICHIGAN

Personal—Dr Gordon H. Yeo, resident physician at the Calumet & Hecla Hospital, Calumet, has gone to the Isthmian Canal Zone——Dr Emory J Brady, a member of the staff of the Kalamazoo State Hospital, has been appointed assistant superintendent of the Newberry State Hospital in the Upper Peninsula

Items About Hospitals.—The Woodward Hospital has been established at 821 Woodward Avenue, Detroit, with accommodation for forty patients The institution is intended as an emergency hospital, and its clientele will be largely from the employees of large manufacturing establishments——West side Hospital, Bay City, was formally opened November 3——Work commenced November 1 on the addition to Nichols Hospital, Battle Creek, which is to be four stories in height, of steel, brick and cement construction and to cost $35,000——Sparrow Hospital, Lansing, was opened to the public, October 27——The supervisors of Shiawassee County have taken steps to provide a county hospital for the care of contagious diseases——The western annex of the Detroit Tuberculosis Sanatorium is completed and ready to receive patients The annex increases the capacity of the institution from twenty to thirty patients

MINNESOTA

Sanatorium Burned—The main building of the Pokegama Tuberculosis Sanatorium, Pine City, was burned November 2, with a loss of about $5,000

State Inebriate Farm Soon to Open.—About the middle of this month the State Farm for Inebriates, Wilmar, will be opened——Dr G H Freeman, assistant superintendent of the St Peter State Hospital, has already assumed his duties at the State Farm

State Board Report.—The annual report of the State Board of Health shows a marked decrease in the deaths of children under five years of age In 1910, 1,709 deaths were reported and in 1911 1,092 Typhoid shows a decrease from 688 to 294, diphtheria from 506 to 335, scarlet fever from 284 to 190 and poliomyelitis from 201 to 54 The two chief causes of death were tuberculosis and pneumonia

Reasons for Vaccination—Dr P M. Hall, health commissioner of Minneapolis, thus crystallizes his reasons for vaccination in Minneapolis

> Past experiences of the Minneapolis health department with small pox.
>
> Present conditions in Eastern cities where an unusually large percentage of cases is of the malignant type
>
> Danger of a patient suffering with small pox in the severe form being shipped into Minneapolis because of the general reputation of the city for having facilities and properly caring for the disease.

MONTANA

State Should Purchase Insane Asylum.—The Silver Bow ledical Society at its meeting, October 23, in Anaconda, nanimously voted in favor of the state purchase of the nsane asylum and grounds at Warm Springs

Outbreak of Typhoid Fever—An outbreak of typhoid fever reported at Malta in the Milk River Valley, where fourteen ases exist Dr Thomas D Tuttle Helena, secretary of the tate Board of Health, who has investigated the situation, tates that the outbreak is due to the contaminated water of ells in the town

Personal.—Dr F D Pease has been appointed city physician f Missoula——Dr A L Martinallo, Butte, has started for taly——Dr and Mrs John B Shaw, Terry, who were eriously injured in a runaway accident, recently, are reported o be convalescent——Dr J P Aylen, chief surgeon of the orthern Pacific Hospital, Missoula, has resigned and moved o Fargo, N Dak——Dr and Mrs Frederick M Poindexter, illon, sailed for Europe, November 28

NEBRASKA

Society Changes Its Name—The local medical society, rganized a year ago in Omaha, has adopted the name, the maha Academy of Medicine and Surgery

New Officers.—Republican Valley Medical Association at xford, November 1 president, Dr Henry Farrell, Axton ecretary Dr P A. Sundbury, Holdrege (reelected)——undy Hitchcock Chase Hays County Medical Association at Vauneta president, Dr W E Stewart, Stratton (reelected) ——Boone County Medical Association at St Edward, November 21 president, Dr Ernest Thelen, Cedar Rapids, secretary reasurer, Dr G W Sullivan, St Edward

Hospital Notes—Dr John Buis Pender, has built and is perating a private hospital for surgical and noncontagious medical cases with accommodation for ten patients——The directrs of the McCook Cooperative Hospital Association have completed the first payment on the building recently purchased y them for hospital purposes——The new Contagious Disase Hospital, Omaha, made possible by the gift of a house at enth and Douglas Streets by the late Anna Wilson, opened o receive patients November 7 The building has thirty three ooms and has two distinct sections, one for scarlet fever and ne for diphtheria

NEW YORK

Convalescent Home for Buffalo—Mrs Frank H. Goodyear as purchased eighty acres of land in Williamsville, on which he will build the Josephine Goodyear Memorial Home for onvalescent Children The home will be constructed on the ottage plan, will be undenominational and accessible for convalescent children from any Buffalo hospital or home

Dispensary Leases College Building—Instead of opening a eparate dispensary, it is reported, Syracuse University College f Medicine has leased its new dispensary building to the yracuse Free Dispensary, in consideration of having its aculty members serve on the staff of that institution The ew dispensary building, which was planned with much care s now rapidly approaching completion

Opposes Death Penalty—The State Superintendent of Prisns, since the release of Albert T Patrick, is reaffirming his ontention of last winter that capital punishment should be bolished He believes that the ends of justice would be served y a sentence of from twenty five years to life and states that here is not a man in the prisons of this state who has served term of twenty five years He also recommends a board of ardons to have the power of recommendation, leaving the overnor the power of granting pardons

New Officers—Queens Nassau Medical Society, November 6 president, Dr W G Frey, Long Island City, secretary reasurer, Dr James S Cooley, Mineola——Clinton County ledical Society, at Plattsburg November 19 president, Dr M Briggs Champlain, secretary, Dr T A Rogers, Plattsburg ——Medical Society of the County of Westchester, at White lains, November 20 president, Dr E W Weber, White lains, secretary, Dr W S Woodruff, Mount Vernon

Personal.—Dr O H Babbitt Auburn has been reelected ail physician and Dr William E Walsh, Auburn, coroner's hysician for Auburn Dr J H Whitbeck, Cayuga, has been lected coroner's physician for the southern part of Cayuga ounty, and Dr A D Stewart, Port Byron to a similar position or the northern section of the county——Dr ack Killen, Binghamton, to avoid running down a foot passenger, steered his automobile into a telegraph pole and was thrown to the ground sustaining serious injuries——Dr William A Binr, state bacteriologist has established a temporary laboratory in St Johnsville, where he will take cultures from the pupils of the schools and factory employees in an endeavor to ascertain the cause and the carriers of diphtheria, which has been so prevalent in the village

New York City

Hospital Moves—The Hospital for the Ruptured and Crippled has moved to its new $1,000 000 building on Forty Second Street east of Second Avenue

Personal—Dr William Seaman Bainbridge has been appointed consulting surgeon to the Tarrytown Hospital Tarrytown N Y——Dr Joseph J O Connell, health officer of the port of New York has sailed for Panama——Dr J Bion Bogart, Brooklyn, who has been seriously ill with septicemia due to an operation wound is reported to be out of danger

New Officers—Medical Society of the County of New York 107th annual meeting, November 25 president, Dr Brooks H Wells, secretary, Dr John Van Doren Young——German Medical Society December 2 president, Dr Gustav Seeligmann, secretary, Dr Martin Rehling——New York Academy of Medicine December 5 president, Dr William L. Polk, recording secretary, Dr Charles F Adams, corresponding secretary, Dr Egbert Le Fevre——Third Ward of Queens Borough Medical Association Dr Charles E Strong Long Island City, temporary chairman Dr E P Lawrence, Flushing, temporary secretary

New Hospital Bulletin—The Woman's Hospital, situated at Cathedral Parkway and One Hundred and Tenth Street, has commenced issuing a bulletin for free distribution among those who are interested in gynecology The scientific articles are contributed by the surgical staff connected with the hospital and based on work done in the hospital and laboratory This laboratory is finely equipped and a salaried pathologist is employed who gives his entire time to the work, opportunity is afforded for the investigation of the most intricate problems Dr J Riddle Goffe is the managing editor of the new publication which will appear occasionally

Mayor Blamed for Increase in Street Accidents—The National Highways Protective Society blames Mayor Gaynor for an increase in the number of street accidents, attributing this increase to the mayor's order forbidding police to arrest drivers or motormen in automobile or street car accidents unless there is evidence that would support a charge of manslaughter or negligence There were during the month of November, 1912 223 accidents, 56 of which were fatal, against 174 accidents with 15 fatalities for the month of November, 1911 Throughout the entire state automobiles severely injured 106, trolley cars ran down 29, and wagons 18

Protests Against Budget Cuts—In making up the budget for 1913 the Board of Aldermen have cut the appropriations of the Board of Education $229 790, the Board of Health, $100,000 and the Department of Charities, Bellevue and the Allied Hospitals, $16,514 Nine medical inspectors and eight supervising nurses have been dropped, leaving 81 000 parochial school children without medical inspection and of these 32 000 will not have even the attention of a supervising nurse Dr Ira S Wile, who was recently appointed to the Board of Education, is making a vigorous protest against this policy, the New York Milk Committee, through its Committee on the Reduction of Infant Mortality, of which Mrs J Borden Harriman is chairman, is up in arms because the work of the milk stations will be crippled by the cutting off of the allowance to the Division of Child Hygiene which would have made possible an expansion of their work The State Board of Charities is also urging on the mayor the necessity of vetoing the action of the aldermen A joint letter has also been sent to the mayor by Comptroller Prendergast, President Mitchell of the Board of Aldermen and Borough President McAneny begging him to veto these cuts and others affecting the social welfare of the people

New Cocain Law Urged—As a result of the recent investigation into the sales of cocain in this city many revelations have been made It has been shown that cocain can be very easily obtained throughout the city, that Manhattan is a distributing station for New Jersey and that the drug may be obtained in Sing Sing prison and in the Tombs As a result of these findings, Judge Swann of the General Sessions who has been dealing with the cases convicted under the present law finds this law very inadequate Although the law as passed in 1907 and amended in 1910 makes the sale of cocain except as provided for, a felony, punishment is limited to a sentence of one year and a fine of $1 000 Other felonies are punishable by imprisonment for at least five years Judge Swann would amend the law so that the mere possession of the drug would be considered a misdemeanor, punishable by a fine of $1,000 or one year in the penitentiary, while the actual sale of cocain should be punishable by imprisonment for at least five years Efforts to have such a law passed at the coming legislature will be made——A renewed effort is being made to suppress the sale of opium and cocain in the new Tenderloin Thus far, convictions have been secured against seven places——It has been discovered that cocain is being sold to a considerable extent to the negroes of the west side

NORTH CAROLINA

New Officers.—High Point Academy of Medicine president, Dr G F Duncan, secretary treasurer, Dr S S Coe, Aurora

New Hospital—The Mercer Hospital Association of Durham has been chartered with an authorized capital of $100,000 The incorporators propose to erect a new general hospital in the city Dr C A. Adams is one of the prime movers in the enterprise

Vital Statistics Law—The State Board of Health, the Medical Society of the State of North Carolina and the medical profession in general, are actively developing public sentiment toward the securing of a vital statistics law for the state at the next session of the legislature, and it is believed that an educated public sentiment will secure the passage of the law

Portrait to be Presented to State Library—Drs J Howell Way, Waynesville, H T Bahnson, Winston Salem, and R H Lewis, Raleigh, the committee appointed by the Medical Society of the State of North Carolina to have prepared a life size oil portrait of the late Dr P L Murphy, Morganton, for presentation to the state library, have had the portrait painted and the presentation will take place in the state capitol at a time to be announced later

Opportunity for Study of Tuberculosis—The superintendent of the State Sanatorium for the Treatment of Tuberculosis, Montrose, is arranging a schedule of clinical and pathologic studies in tuberculosis for the benefit of physicians of the state the course to be given at the sanatorium, later in the winter Especial stress will be laid on the diagnosis of tuberculosis and efforts will also be made to send incipient cases early to the institution

Personal.—Dr Joseph Akerman, Wilmington, has succeeded Dr C D Bell Wilmington, as coroner of New Hanover County ——Dr Lyle S Booker, Durham, announces that after December 1, he will limit his practice to surgery——Dr Albert Anderson, Raleigh, has been appointed a trustee of the Rainey Library——Dr M R Gibson, *who has been taking post* graduate studies in Baltimore, has returned to his home in Maxton where he will confine his practice to the diseases of the eye, ear, nose and throat

PENNSYLVANIA
